Abstract

In this paper we investigate in detail the correspondence between E_{10} and Romans' massive deformation of type IIA supergravity. We analyse the dynamics of a non-linear sigma model for a spinning particle on the coset space $E_{10}/K(E_{10})$ and show that it reproduces the dynamics of the bosonic as well as the fermionic sector of the massive IIA theory, within the standard truncation. The mass deformation parameter corresponds to a generator of E_{10} outside the realm of the generators entering the usual $D = 11$ analysis, and is naturally included without any deformation of the coset model for $E_{10}/K(E_{10})$. Our analysis thus provides a dynamical unification of the massless and massive versions of type IIA supergravity inside E_{10}. We discuss a number of additional and general features of relevance in the analysis of any deformed supergravity in the correspondence to Kac-Moody algebras, including recently studied deformations where the trombone symmetry is gauged.

1 Introduction

Deformations of supergravity theories form an important part of the low energy limit of M-theory. By a deformed supergravity we mean a theory that is different from standard Kaluza–Klein reductions of maximal $D = 11$ supergravity (to which we restrict in this paper). Often, these theories cannot even be obtained by other types of reductions or compactifications from $D = 11$ and are therefore to be interpreted as genuine new low energy actions for M-theory. One of the pertinent features of deformed supergravity theories is that they support domain wall solutions which are required to maintain invariance under the duality symmetries expected from an underlying string theory description. The most prominent example of this phenomenon is the D8-brane of type IIA string theory that can be reached from lower-dimensional branes by sequences of T-dualities [1]. However, there is no corresponding supergravity solution in undeformed type IIA supergravity in $D = 10$. Only when considering a (mass) deformation of type IIA supergravity (constructed by Romans for different reasons [2]) can one accommodate the D8-brane [1]. Similar results have been obtained for many other deformed supergravity theories, most of which are so-called gauged supergravities, see for example [3].[1]

---

[1] Another common deformation is to add a cosmological constant but this is not always consistent with supersymmetry. Notably in $D = 11$ the cosmological term is disallowed [4].

Therefore any attempt at describing M-theory, at least at low energies, should be able to reproduce these deformed supergravity theories. One possible approach to M-theory is via Kac–Moody symmetries, notably E_{10} [5–8] and E_{11} [5–7, 9–11]. Considering suitably truncated non-linear realizations of these infinite-dimensional symmetries has led to perfect agreement for the spectra of fields appearing in undeformed (super-)gravity theories in various dimensions, where the spectral analysis is carried out using a so-called level decomposition [9, 8, 12–14]. For E_{10} there exists a one-dimensional sigma model whose geodesic equations of motion are conjectured to describe the dynamics of M-theory and this has been verified in a low level approximation for undeformed maximal $D = 11$ supergravity [8, 15]. A more precise form of the conjecture states that one has to consider a constrained geodesic, which mirrors the canonical constraints present in supergravity [16]. It has also been analysed how to add fermions to the geodesic sigma model, with good agreement for both kinematics and dynamics [17–21]. Similarly, for E_{11} a dynamical realization has been discussed [9] based on non-linear realizations and an algebraic construction of infinitesimal diffeomorphisms [22, 23] and it was argued that this construction agrees with undeformed supergravity.

In a recent development it was observed that the spectral analysis of E_{10} and E_{11} also yields all the fields required for deformed (maximal) supergravity theories in various dimensions [24–26].[2] These arise via forms of high rank, specifically $(D-1)$-forms for deformations in D dimensions.[3] It is worthwhile to emphasize that the Kac–Moody generators associated to the usual gauge deformation parameters are never part of the underlying E_8 or E_9 algebra but genuine E_{10} (and hence E_{11}) generators. This is in contradistinction to the fields of the undeformed theory.

This paper addresses the question to what extent the deformation parameters also appear correctly in the dynamics of the geodesic model of E_{10}. This will be done specifically in the case of the Romans' deformed IIA supergravity theory, where the mass m is the only deformation parameter. It corresponds to a generator on level $\ell = 4$ in parlance relevant for $D = 11$ supergravity and hence outside the realm of generators considered usually. The analysis here will be carried out both for bosons and for fermions and we will show agreement within the expected limitations of any known Kac–Moody/supergravity correspondence. Importantly, all terms associated with the mass deformation work perfectly.

The mass parameter was already identified for cosmological billiards [34] and in the level decomposition in [14] and studied in [35, 36], with an emphasis on the D8 brane in [37, 38]. The present analysis completes the picture by giving a complete and detailed account of the fermions and bosons (as well as their supersymmetry) up to the level of the mass parameter in an $\mathfrak{sl}(9,\mathbb{R}) \subset \mathfrak{e}_{10} := \text{Lie } E_{10}$ decomposition. Furthermore, our analysis highlights several features relevant to deformed supergravity.

---

[2] Related work for non-maximal supergravity can be found in [27–29].

[3] In the case of gauged supergravity, there are (quadratic) constraints on these $(D-1)$-forms [30–32] which appear in the tables of E_{11} (only) as D-forms [24–26]. For E_{10} the quadratic constraints appear to lie in a multiplet of constraints [33] together with the other canonical constraints.

1. The E_{10} coset model and fermionic representations we use are completely *unaltered* with respect to the ones successfully employed for the comparison with $D = 11$ supergravity and undeformed IIA and IIB supergravity [36]. In particular, there is no deformation of the Kac–Moody structure underlying this algebraic approach to M-theory. This is different from proposals for the relation between E_{11} and gauged supergravity [24, 26].

2. In our approach the mass deformation can be included in the sigma model formulation without deforming the E_{10} structure because the comparison always takes place in terms of *gauge-fixed* variables on both the supergravity and the Kac–Moody side. This allows to maintain the usual derivative and coset variables, as well as the gauge algebra structure. The gauge fixing re-enters in a consistent way via constraints. These issues are discussed in detail in Section 5. It is important to note that although this gauge fixing is chosen because it makes the E_{10}/supergravity correspondence particularly transparent, we of course expect that ultimately the physics should be independent of any particular gauge.

3. The mass (or more generally all deformation parameters [33]) arise as *integration constants* of the geodesic equations in a consistent truncation. This is in accordance with previous results in the context of massive IIA supergravity [39].

4. We analyse in addition the deformed supergravity theory obtained by gauging a global scaling symmetry of the equations of motion. This is known as trombone gauging [40, 41] and has recently attracted attention in the E_{10} and E_{11} context [42]. Our findings suggest that the association of the deformation parameter with a certain mixed symmetry tensor appearing in the level decomposition is problematic.

5. As a by-product of our analysis we derive the commutation relations of $\mathfrak{e}_{10}$ up to $\mathfrak{sl}(10,\mathbb{R})$ level $\ell = 4$, confirming an earlier computer algebra analysis [43]. This result is then used to construct the $\ell = 4$ action of $\mathfrak{k}(\mathfrak{e}_{10})$ on the Dirac spinor and vector-spinor representations of $\mathfrak{k}(\mathfrak{e}_{10})$. These results are presented in Appendix E.

This paper is structured as follows. We begin by presenting massive IIA supergravity in our conventions in Section 2, giving the complete Lagrangian including the fermionic sector. In this section we also provide the explicit form of the supersymmetry variations that leave the Lagrangian invariant. Then we proceed in Section 3 to introduce the Kac-Moody algebra $\mathfrak{e}_{10}$ in the $\mathfrak{sl}(9,\mathbb{R})$ level decomposition, relevant to the comparison with Romans' theory.

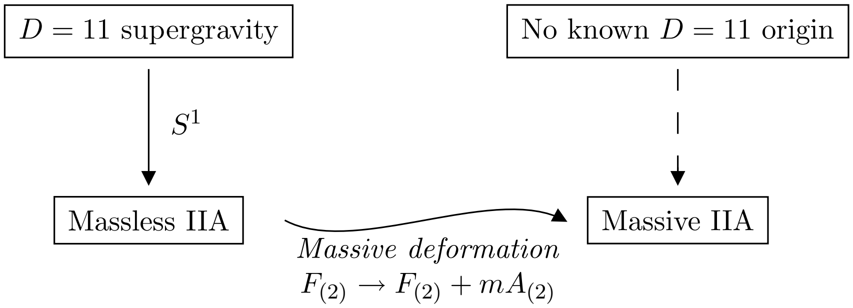

Figure 1: *Massive IIA supergravity from $D = 11$ supergravity: Massive type IIA supergravity is obtained as a deformation of the standard type IIA supergravity, but unlike the latter, it does not possess any known eleven-dimensional origin. See Figure 2 for a pictorial description of how $D = 11$ supergravity and massive IIA supergravity are unified inside E_{10}.*

Here we also introduce the bosonic and fermionic parts of the E_{10}-invariant sigma model, and present their respective equations of motion. Section 4 is devoted to the comparison between the equations of motion of massive IIA supergravity and those of the geodesic sigma model for $E_{10}/K(E_{10})$. Here we establish the dictionary which yields a dynamical correspondence between the two models in the bosonic and fermionic sector. After the E_{10}/massive IIA correspondence is validated we discuss in more detail in Section 5 its implications, as well as some of the salient features of the analyis, including a derivation of the bosonic supersymmetry variations from the structure of $\mathfrak{e}_{10}$. Finally, in Section 6 we discuss the relation between our work and the recently proposed gauging of the so-called trombone symmetry. Since our analysis is quite technical and involves numerous lengthy calculations, we have for the benefit of the reader relegated most of the detailed calculations to appendices, where we for completeness also present an explicit analysis of $\mathfrak{e}_{10}$ and $\mathfrak{k}(\mathfrak{e}_{10})$ at $\mathfrak{sl}(10,\mathbb{R})$ level four.

2 Massive IIA supergravity

Massive type IIA supergravity was first constructed by Romans [2] by deforming the standard type IIA supergravity through a Stückelberg mechanism, giving a mass to the two-form potential through the replacement $F_{\mu\nu} \to F_{\mu\nu} + mA_{\mu\nu}$, where $F_{\mu\nu} = 2\partial_{[\mu}A_{\nu]}$. The potential A_μ can then be gauged away by a gauge transformation of $A_{\mu\nu}$. This process unfortunately obscures the massless limit to recover the standard IIA theory [44–46] as some of the supersymmetry variations involve a coefficient m^{-1}. This is remedied by a field redefinition presented in [39, 47], that we will make use of in this paper.

Moreover, a more democratic version of massive type IIA is given in [47, 48], in which every form field comes with its dual. In particular, it involves a nine-form as a (potential) dual to the mass (seen as a field strength). This democratic formulation makes explicit the striking feature of massive IIA supergravity that it allows the existence of a D8-brane, that is known to exist in type IIA string theory. Indeed, this feature requires a nine-form potential that couples to the D8-brane, and accordingly does not appear in massless IIA supergravity. Although in this paper we will not use directly the democratic formulation, we will employ the field redefinitions used in [39] in order to clarify the massless limit.

In addition, as a motivation for the present work, one also finds a nine-form in a certain decomposition of E_{10}, as will be developed in the next section, and this nine-form appears in the $E_{10}/K(E_{10})$ Lagrangian in the same way as the mass term in the massive IIA Lagrangian. Massive IIA supergravity has in common with many other deformed maximal supergravities that it does not possess any known higher dimensional origin, as illustrated in Figure 1. A consequence of the present work is to show that, although they are not related by dimensional reduction, eleven dimensional supergravity and massive IIA supergravity have the same E_{10} origin as displayed in Figure 2, see also [34, 14, 37].[4]

2.1 Romans' theory

In this section, and throughout the paper, the curved ten-dimensional space-time indices are denoted by μ and decompose into time t and nine spatial indices m. The flat indices are similarly denoted by $\alpha = (0, a)$. Our space-time signature is $(- + \ldots +)$. More details on the conventions can be found in Appendix A.

The complete supersymmetric Lagrangian (up to second order in fermions) in Einstein frame is given by the sum of a bosonic and a fermionic part, $\mathcal{L} = \mathcal{L}^{[B]} + \mathcal{L}^{[F]}$. The bosonic sector contains a metric $G_{\mu\nu}$, a dilaton ϕ, a one-form $A_{(1)}$ with field strength $F_{(2)}$, a two-form $A_{(2)}$ with field strength $F_{(3)}$, a three-form $A_{(3)}$ with field strength $F_{(4)}$, and a real mass parameter m. The bosonic part of the Lagrangian reads

$$\begin{aligned} \mathcal{L}^{[B]} &= \sqrt{-G}\left[R - \frac{1}{2}|\partial\phi|^2 - \frac{1}{4}e^{3\phi/2}|F_{(2)}|^2 - \frac{1}{12}e^{-\phi}|F_{(3)}|^2 - \frac{1}{48}e^{\phi/2}|F_{(4)}|^2 - \frac{1}{2}m^2 e^{5\phi/2}\right] \\ &+ \varepsilon^{\mu_1\cdots\mu_{10}}\left[\frac{1}{144}\partial_{\mu_1}A_{\mu_2\mu_3\mu_4}\partial_{\mu_5}A_{\mu_6\mu_7\mu_8}A_{\mu_9\mu_{10}} + \frac{m}{288}\partial_{\mu_1}A_{\mu_2\mu_3\mu_4}A_{\mu_5\mu_6}A_{\mu_7\mu_8}A_{\mu_9\mu_{10}}\right. \\ &\qquad\left. + \frac{m^2}{1280}A_{\mu_1\mu_2}A_{\mu_3\mu_4}A_{\mu_5\mu_6}A_{\mu_7\mu_8}A_{\mu_9\mu_{10}}\right]. \end{aligned} \tag{2.1a}$$

---

[4] We note that the search for an eleven-dimensional origin of the Romans mass parameter, and hence the D8-brane, has led to studies of an M-theory M9-brane which is meant to exist in the presence of one Killing direction and then reduces to the IIA D8-brane, see e.g. [49, 50].

$$\begin{tikzcd}
& \boxed{E_{10}} \arrow[dl, "\ell_1"'] \arrow[dr, "(\ell_1,\ell_2)"] & \\
\boxed{\mathcal{L}_{\text{SUGRA}_{11}} \subset \mathcal{L}_{E_{10}/K(E_{10})}} \arrow[rr, "\text{`Dimensional Reduction'}", "\ell_2"'] & & \boxed{\mathcal{L}_{\text{mIIA}} \subset \mathcal{L}_{E_{10}/K(E_{10})}}
\end{tikzcd}$$

Figure 2: *This picture describes the common E_{10} origin of eleven-dimensional supergravity and massive type IIA supergravity. First, if one considers a level ℓ_1 decomposition of E_{10} with respect to A_9 (cf. Figure 3), one sees that the first levels ($\ell_1 = 0$ to $\ell_1 = 3$) of an $E_{10}/K(E_{10})$ sigma-model correspond to a truncated version of eleven-dimensional supergravity, with Lagrangian $\mathcal{L}_{\text{SUGRA}_{11}}$ [8]. Taking this as a starting point, we can perform an additional level ℓ_2 decomposition on the sigma model. On the lower ℓ_1 levels ($\ell_1 = 0$ to $\ell_1 = 3$) this is equivalent to a dimensional reduction of eleven-dimensional supergravity, which gives massless IIA supergravity (cf. Figure 1). However, if one includes one of the generators appearing at $\ell_1 = 4$, this leads to a theory that coincides with a truncated version of massive IIA supergravity, with Lagrangian $\mathcal{L}_{\text{mIIA}}$. This procedure is equivalent to a multi-level (ℓ_1, ℓ_2) decomposition of E_{10} with respect to A_8. More details on this are given in Section 3.2. By similar arguments, one could add IIB supergravity to this picture, in the sense that it has the same E_{10} origin in a level decomposition with respect to $A_8 \times A_1$, i.e. with respect to node 8 in the Dynkin diagram in Figure 3 [51].*

Here, we already point out that the massive deformation induces a positive definite potential on the scalar sector. This is in marked contrast to what happens for gauged supergravity in lower dimensions where the scalar potential is generically indefinite [30, 32], causing also problems in the connection to E_{10} [33].

On the fermionic side, we have two gravitini, combined in a single 10×32 component vector-spinor ψ_μ, and two dilatini, combined in a single 32 component Dirac-spinor λ, which decompose into two fields of opposite chirality under $SO(1,9)$. For this sector the Lagrangian takes the form

$$\begin{aligned}
\mathcal{L}^{[F]} \;&=\; i\sqrt{-G}\,\Bigg[-2\bar{\psi}_{\mu_1}\Gamma^{\mu_1\cdots\mu_3}D_{\mu_2}\psi_{\mu_3} - \bar{\lambda}\Gamma^{\mu}D_{\mu}\lambda + \partial_{\mu_1}\phi\bar{\lambda}\Gamma^{\mu_2}\Gamma^{\mu_1}\psi_{\mu_2} \\
&+\; \frac{1}{4}e^{3\phi/4}F_{\mu_1\mu_2}\Big(\bar{\psi}_{[\nu_1}\Gamma^{\nu_1}\Gamma^{\mu_1\mu_2}\Gamma^{\nu_2}\Gamma_{10}\psi_{\nu_2]} - \frac{3}{2}\bar{\lambda}\Gamma^{\nu}\Gamma^{\mu_1\mu_2}\Gamma_{10}\psi_{\nu} + \frac{5}{8}\bar{\lambda}\Gamma^{\mu_1\mu_2}\Gamma_{10}\lambda\Big) \\
&+\; \frac{1}{12}e^{-\phi/2}F_{\mu_1\cdots\mu_3}\Big(\bar{\psi}_{[\nu_1}\Gamma^{\nu_1}\Gamma^{\mu_1\cdots\mu_3}\Gamma^{\nu_2}\Gamma_{10}\psi_{\nu_2]} - \bar{\lambda}\Gamma^{\nu}\Gamma^{\mu_1\cdots\mu_3}\Gamma_{10}\psi_{\nu}\Big)
\end{aligned}$$

$$\begin{aligned} - & \frac{1}{48} e^{\phi/4} F_{\mu_1\ldots\mu_4}\Big(\bar{\psi}_{[\nu_1}\Gamma^{\nu_1}\Gamma^{\mu_1\ldots\mu_4}\Gamma^{\nu_2}\psi_{\nu_2]} - \frac{1}{2}\bar{\lambda}\Gamma^{\nu}\Gamma^{\mu_1\ldots\mu_4}\psi_{\nu} + \frac{3}{8}\bar{\lambda}\Gamma^{\mu_1\ldots\mu_4}\lambda\Big) \\ + & \frac{21}{8} m e^{5\phi/4}\bar{\lambda}\lambda - \frac{1}{2} m e^{5\phi/4}\bar{\psi}_{\mu_1}\Gamma^{\mu_1\mu_2}\psi_{\mu_2} + \frac{5}{4} m e^{5\phi/4}\bar{\lambda}\Gamma^{\mu}\psi_{\mu}\Bigg]. \end{aligned} \tag{2.1b}$$

The last line contains the explicit mass terms for the fermions. There are also implicit mass deformations in the definitions of the field strength in terms of the gauge potentials

$$\begin{aligned} F_{\mu_1\mu_2} &= 2\partial_{[\mu_1}A_{\mu_2]} + mA_{\mu_1\mu_2}\,, \\ F_{\mu_1\mu_2\mu_3} &= 3\partial_{[\mu_1}A_{\mu_2\mu_3]}\,, \\ F_{\mu_1\mu_2\mu_3\mu_4} &= 4\partial_{[\mu_1}A_{\mu_2\mu_3\mu_4]} + 4A_{[\mu_1}F_{\mu_2\mu_3\mu_4]} + 3mA_{[\mu_1\mu_2}A_{\mu_3\mu_4]}\,. \end{aligned} \tag{2.2}$$

In the Lagrangian, they are contracted without additional factors, for example

$$|F_{(2)}|^2 = F_{\mu_1\mu_2}F^{\mu_1\mu_2}. \tag{2.3}$$

In (2.2) we see the characteristic feature of a deformed theory that the usual tensor hierarchy of gauge fields is broken: there are forms coupling to potentials of higher degree but only through terms proportional to the deformation parameter. The tangent space field strengths are defined as usual by conversion with the (inverse) vielbein $e_{\alpha}{}^{\mu}$, for example $F_{\alpha_1\alpha_2} = e_{\alpha_1}{}^{\mu_1}e_{\alpha_2}{}^{\mu_2}F_{\mu_1\mu_2}$. Flat indices are raised and lowered with the Minkowski metric and we will often write contracted flat spatial indices on the same level.

2.2 Supersymmetry variations

The supersymmetry variations leaving (2.1) invariant, up to total derivatives and higher order fermion terms, are listed in this section. For the fermions, they read

$$\begin{aligned} \delta_{\varepsilon}\psi_{\mu} &= D_{\mu}\varepsilon - \frac{1}{32} m e^{5\phi/4}\Gamma_{\mu}\varepsilon - \frac{1}{64} e^{3\phi/4} F_{\nu\rho}(\Gamma_{\mu}{}^{\nu\rho} - 14\delta_{\mu}^{[\nu}\Gamma^{\rho]})\Gamma_{10}\varepsilon \\ &\quad + \frac{1}{96} e^{-\phi/2} F_{\nu\rho\sigma}\big(\Gamma_{\mu}{}^{\nu\rho\sigma} - 9\delta_{\mu}^{[\nu}\Gamma^{\rho\sigma]}\big)\Gamma_{10}\varepsilon \\ &\quad + \frac{1}{256} e^{\phi/4} F_{\nu\rho\sigma\gamma}\big(\Gamma_{\mu}{}^{\nu\rho\sigma\gamma} - \frac{20}{3}\delta_{\mu}^{[\nu}\Gamma^{\rho\sigma\gamma]}\big)\varepsilon, \end{aligned} \tag{2.4}$$

and

$$\begin{aligned} \delta_{\varepsilon}\lambda &= \frac{1}{2}\partial_{\mu}\phi\Gamma^{\mu}\varepsilon + \frac{5}{8} e^{5\phi/4} m\,\varepsilon - \frac{3}{16} e^{3\phi/4} F_{\mu\nu}\Gamma^{\mu\nu}\Gamma_{10}\varepsilon \\ &\quad - \frac{1}{24} e^{-\phi/2} F_{\mu\nu\rho}\Gamma^{\mu\nu\rho}\Gamma_{10}\varepsilon + \frac{1}{192} e^{\phi/4} F_{\mu\nu\rho\sigma}\Gamma^{\mu\nu\rho\sigma}\varepsilon, \end{aligned} \tag{2.5}$$

while for the bosons we have

$$\delta_{\varepsilon} e_{\mu}{}^{\alpha} = i\bar{\varepsilon}\Gamma^{\alpha}\psi_{\mu}, \qquad \delta_{\varepsilon}\phi = i\bar{\lambda}\varepsilon, \tag{2.6}$$

and

$$\delta_\varepsilon A_\mu = \theta_\mu, \qquad \delta_\varepsilon A_{\mu\nu} = \theta_{\mu\nu}, \qquad \delta_\varepsilon A_{\mu\nu\rho} = \theta_{\mu\nu\rho} + 6A_{[\mu}\theta_{\nu\rho]}, \tag{2.7}$$

where

$$\begin{aligned}
\theta_\mu &:= ie^{-3\phi/4}\left(-\bar{\psi}_\mu - \frac{3}{4}\bar{\lambda}\Gamma_\mu\right)\Gamma_{10}\varepsilon, \\
\theta_{\mu\nu} &:= ie^{\phi/2}\left(2\,\bar{\psi}_{[\mu}\Gamma_{\nu]} - \frac{1}{2}\bar{\lambda}\Gamma_{\mu\nu}\right)\Gamma_{10}\varepsilon, \\
\theta_{\mu\nu\rho} &:= ie^{-\phi/4}\left(3\,\bar{\psi}_{[\mu}\Gamma_{\nu\rho]} + \frac{1}{4}\bar{\lambda}\Gamma_{\mu\nu\rho}\right)\varepsilon.
\end{aligned} \tag{2.8}$$

Note that the mass only enters in the supersymmetry variations of the fermions.

3 On E_{10} and the geodesic sigma model for $E_{10}/K(E_{10})$

In this section we give some basic properties of the Kac–Moody algebra $\mathfrak{e}_{10}$ and explain how to construct a non-linear sigma model for geodesic motion on the infinite-dimensional coset space $E_{10}/K(E_{10})$. To this end we shall slice up the adjoint representation of $\mathfrak{e}_{10}$ in a multi-level decomposition, suitable to reveal the field content of massive IIA supergravity [35, 14]. In order to incorporate also the fermionic sector in the sigma model, we will analyse the relevant (unfaithful) Dirac-spinor and vector-spinor representations of $\mathfrak{k}(\mathfrak{e}_{10})$ up to the desired level.[5] For a more detailed discussion of the general $\mathfrak{e}_{10}$ methods employed here we refer to the review papers [52–54], for more information about $\mathfrak{k}(\mathfrak{e}_{10})$ see [17–19, 21], and for a mathematical introduction to Kac-Moody algebras the canonical reference is [55].

3.1 Generalities of the Kac-Moody algebra $\mathfrak{e}_{10}$

Here we discuss the salient features of the hyperbolic Kac–Moody algebra $\mathfrak{e}_{10}$, the group of which we shall denote by E_{10}. We will furthermore only be concerned with the split real form $\mathfrak{e}_{10} := \mathfrak{e}_{10(10)}(\mathbb{R})$ of the complex Lie algebra $\mathfrak{e}_{10}(\mathbb{C})$. The split real form is generated by ten triples (e_i, f_i, h_i), $i = 1, \ldots, 10$, of Chevalley generators, each triple making up a distinguished subalgebra,

$$\mathfrak{sl}_i(2,\mathbb{R}) = \mathbb{R}f_i \oplus \mathbb{R}h_i \oplus \mathbb{R}e_i \subset \mathfrak{e}_{10}. \tag{3.1}$$

---

[5] The vector-spinor representation Ψ that we construct (following [17–19, 21]) is unfaithful in the sense that it is a finite-dimensional representation of the infinite-dimensional algebra $\mathfrak{k}(\mathfrak{e}_{10})$. However, we stress that in the spirit of the original 'gradient conjecture' of [8] it would be more natural to regard Ψ as the first component in a faithful (infinite-dimensional) representation $\hat{\Psi} := (\Psi, \partial_a\Psi, \ldots)$ of $\mathfrak{k}(\mathfrak{e}_{10})$, where the remaining components encode spatial gradients of the gravitino Ψ [18, 19]. As the employed **320** representation is a fully consistent representation of $K(E_{10})$, its transformations (that will be shown to be in good agreement with supergravity below) will never leave this 320-dimensional (invariant) representation space. A reconciliation of this with the gradient conjecture is beyond the scope of this paper.

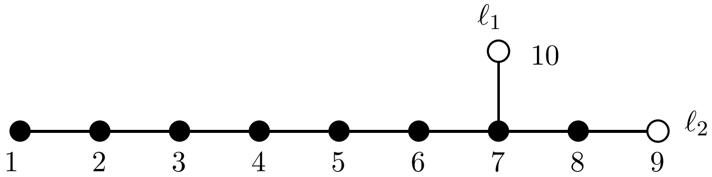

Figure 3: *The Dynkin diagram of* $\mathfrak{e}_{10}$ *with the nodes associated with the level decomposition indicated in white.*

These subalgebras are intertwined inside $\mathfrak{e}_{10}$ according to the stucture of the Dynkin diagram in Figure 3. The full structure of the algebra follows from multiple commutators of the form $[e_{i_1}, [e_{i_2}, \cdots [e_{i_{k-1}}, e_{i_k}] \cdots]]$ (and similarly for the f_i's) modulo the so-called Serre relations. We have the standard triangular decomposition

$$\mathfrak{e}_{10} = \mathfrak{n}_- \oplus \mathfrak{h} \oplus \mathfrak{n}_+, \tag{3.2}$$

where $\mathfrak{h} = \sum_i \mathbb{R}h_i$ is the Cartan subalgebra and the nilpotent parts $\mathfrak{n}_\pm$ are generated by the e_i's and f_i's, respectively. In other words, the subspace $\mathfrak{n}_+$ contains the positive step operators, while $\mathfrak{n}_-$ contains the negative step operators.

The maximal compact subalgebra $\mathfrak{k}(\mathfrak{e}_{10}) \subset \mathfrak{e}_{10}$ is defined as the subalgebra which is pointwise fixed by the Chevalley involution ω,

$$\mathfrak{k}(\mathfrak{e}_{10}) := \{x \in \mathfrak{e}_{10} \mid \omega(x) = x\}, \tag{3.3}$$

where ω is defined through its action on each triple (e_i, f_i, h_i):

$$\omega(e_i) = -f_i, \qquad \omega(f_i) = -e_i, \qquad \omega(h_i) = -h_i. \tag{3.4}$$

By virtue of the existence of $\mathfrak{k}(\mathfrak{e}_{10})$ we have the standard Iwasawa and Cartan decompositions (direct sums of vector spaces),

$$\begin{aligned} \mathfrak{e}_{10} &= \mathfrak{k}(\mathfrak{e}_{10}) \oplus \mathfrak{h} \oplus \mathfrak{n}_+, && \text{(Iwasawa)} \\ \mathfrak{e}_{10} &= \mathfrak{k}(\mathfrak{e}_{10}) \oplus \mathfrak{p}, && \text{(Cartan)}, \end{aligned} \tag{3.5}$$

which will both be of importance in subsequent sections. The generators belonging to $\mathfrak{p}$ are those which are anti-invariant under ω. Note that the subspace $\mathfrak{p}$ does not close under the Lie bracket, but rather transforms in a representation of $\mathfrak{k}$. On the other hand, the subspace $\mathfrak{b} := \mathfrak{h} \oplus \mathfrak{n}_+$ is a subalgebra of $\mathfrak{e}_{10}$, known as a *Borel subalgebra*. Using the Chevalley involution we project an arbitrary generator $x \in \mathfrak{e}_{10}$ onto the different subspaces of the Cartan decomposition according to

$$\begin{aligned} \mathcal{Q} &:= \frac{1}{2}\big[x+\omega(x)\big] \;\in\; \mathfrak{k}(\mathfrak{e}_{10}), \\ \mathcal{P} &:= \frac{1}{2}\big[x-\omega(x)\big] \;\in\; \mathfrak{p}. \end{aligned} \tag{3.6}$$

The Cartan matrix A of $\mathfrak{e}_{10}$, deduced from the Dynkin diagram in Figure 3, induces an indefinite and non-degenerate bilinear form $\langle\cdot|\cdot\rangle$ on $\mathfrak{h}$ as follows

$$\langle h_i|h_j\rangle := A_{ij}. \tag{3.7}$$

By invariance, this bilinear form can be extended to all of $\mathfrak{e}_{10}$, and in particular for the Chevalley generators we have

$$\langle e_i|f_j\rangle = \delta_{ij}, \qquad \langle h_i|e_j\rangle = 0, \qquad \langle h_i|f_j\rangle = 0. \tag{3.8}$$

This bilinear form will be used in subsequent sections to construct a manifestly $\mathfrak{e}_{10}$-invariant Lagrangian.

3.2 The IIA level decomposition of $\mathfrak{e}_{10}$ and $\mathfrak{k}(\mathfrak{e}_{10})$

To elucidate the relation between the infinite-dimensional algebra $\mathfrak{e}_{10}$ and the field content of massive type IIA supergravity, we shall perform a decomposition of the adjoint representation of $\mathfrak{e}_{10}$ into representations of the finite-dimensional subalgebra $A_8 \cong \mathfrak{sl}(9,\mathbb{R})$, defined by nodes $1,\ldots,8$ in the Dynkin diagram in Figure 3 (see also [14]). Each generator of $\mathfrak{e}_{10}$ is then represented as an $\mathfrak{sl}(9,\mathbb{R})$-tensor, say $X_{a_1\cdots a_k} \in \mathfrak{e}_{10}$, where the indices are interpreted as the flat spatial indices of the ten-dimensional supergravity theory and transform in a given irreducible representation described by a set of Dynkin indices, or equivalently by a Young tableau. Since $\mathfrak{e}_{10}$ is of rank 10 and A_8 is of rank 8, this decomposition is a multi-level $\ell := (\ell_1,\ell_2)$-decomposition, with ℓ_1 being associated with the exceptional node in the Dynkin diagram, while ℓ_2 corresponds to the rightmost node.

A useful alternative point of view on this decomposition is to first perform only the ℓ_1 decomposition with respect to the horizontal $A_9 \cong \mathfrak{sl}(10,\mathbb{R})$ subalgebra consisting of nodes 1 through to 9 in Figure 3. As is well-known, at low ℓ_1 levels, this decomposition gives rise to the field content of eleven-dimensional supergravity [8,15]. We can then view the additional decomposition with respect to ℓ_2 as a 'dimensional reduction' from $D=11$ to $D=10$. It is this point of view which enables us to relate the mass term in massive type IIA supergravity to a generator of $\mathfrak{e}_{10}$ at level $\ell_1=4$ in the standard 'M-theory decomposition' of [8,15,37]. This is intriguing since in $D=11$ the matching between supergravity and $\mathfrak{e}_{10}$ has only been successful up to $\ell_1=3$. Thus, the mass term in $D=10$ provides a non-trivial check of $\mathfrak{e}_{10}$ beyond its '$\mathfrak{sl}(10,\mathbb{R})$-covariantized $\mathfrak{e}_8$' subset, i.e. the generators of $\mathfrak{e}_8$ and their images under (the Weyl group of) $\mathfrak{sl}(10,\mathbb{R})$.

The relation between $\mathfrak{e}_{10}$ and $\mathfrak{e}_{11}$ and the mass deformation parameter of type IIA supergravity has been pointed out in various earlier references. In [35] the massive type IIA theory was reformulated as a non-linear realization where the mass term was associated with a certain nine-form generator of $\mathfrak{e}_{11}$. Shortly after, in [34], it was observed that the mass term in Romans' theory corresponds to a positive real root of $\mathfrak{e}_{10}$. This was further elaborated upon in [36] where a truncated version of massive type IIA supergravity in an $SO(9,9)$-covariant formulation was shown to be equivalent to the sigma model for $\mathfrak{e}_{10}$ in a level decomposition with respect to a $D_9 \cong \mathfrak{so}(9,9)$-subalgebra. This analysis mainly focused on the bosonic sector, but a preliminary analysis of the fermionic sector was initiated by restricting to the zeroth level of the $\mathfrak{e}_{10}$-decomposition. It was also pointed out in [14, 37, 54] that the mass term has a natural interpretation as a generator at level four in a decomposition of $\mathfrak{e}_{10}$ with respect to $A_8 \cong \mathfrak{sl}(9,\mathbb{R})$. From this point of view, the kinetic term in the sigma model associated with this generator naturally gives rise to the mass term of type IIA upon dimensional reduction. This is the viewpoint which we extend in the present work.

3.2.1 Generators of $\mathfrak{e}_{10}$

The level decomposition of $\mathfrak{e}_{10}$ under the $A_8 \cong \mathfrak{sl}(9,\mathbb{R})$ subalgebra up to level $(\ell_1,\ell_2)=(4,1)$ is shown in Table 1. At level $(\ell_1,\ell_2)=(0,0)$ there is a copy of $\mathfrak{gl}(9,\mathbb{R}) = \mathfrak{sl}(9,\mathbb{R}) \oplus \mathbb{R}$, as well as a scalar generator associated with the dilaton. The commutation relations at this level are $(a,b=1,\ldots,9)$

$$\begin{aligned}
[K^a{}_b, K^c{}_d] &= \delta^c_b K^a{}_d - \delta^a_d K^c{}_b, \\
[T, K^a{}_b] &= 0,
\end{aligned} \tag{3.9}$$

and the bilinear form reads

$$\langle K^a{}_b | K^c{}_d\rangle = \delta^a_d\delta^c_b - \delta^a_b\delta^c_d, \qquad \langle T|T\rangle = \frac{1}{2}, \qquad \langle T|K^a{}_b\rangle = 0. \tag{3.10}$$

All objects transform as $\mathfrak{gl}(9,\mathbb{R})$ tensors in the obvious way. The positive level generators are obtained through multiple commutators between the (fundamental) generators E^a and E^{ab} on levels $(0,1)$ and $(1,0)$, respectively. For example, the generator on level $(1,1)$ is obtained simply as the commutator

$$[E^{ab}, E^c] = E^{abc}. \tag{3.11}$$

All the remaining relevant commutators up to level $(4,1)$ are given in Appendix B.1. No generators of $\mathfrak{e}_{10}$ appear on mixed positive and negative levels, meaning that for any $X_\ell \in \mathfrak{e}_{10}$

(ℓ_1, ℓ_2)	$\mathfrak{sl}(9,\mathbb{R})$ Dynkin labels	Generator of $\mathfrak{e}_{10}$
$(0,0)$	$[1,0,0,0,0,0,0,1] \oplus [0,0,0,0,0,0,0,0]$	$K^a{}_b$
$(0,0)$	$[0,0,0,0,0,0,0,0]$	T
$(0,1)$	$[0,0,0,0,0,0,0,1]$	E^a
$(1,0)$	$[0,0,0,0,0,0,1,0]$	$E^{a_1a_2}$
$(1,1)$	$[0,0,0,0,0,1,0,0]$	$E^{a_1a_2a_3}$
$(2,1)$	$[0,0,0,1,0,0,0,0]$	$E^{a_1\cdots a_5}$
$(2,2)$	$[0,0,1,0,0,0,0,0]$	$E^{a_1\cdots a_6}$
$(3,1)$	$[0,1,0,0,0,0,0,0]$	$E^{a_1\cdots a_7}$
$(3,2)$	$[1,0,0,0,0,0,0,0]$	$E^{a_1\cdots a_8}$
$(3,2)$	$[0,1,0,0,0,0,0,1]$	$E^{a_0\vert a_1\cdots a_7}$
$(4,1)$	$[0,0,0,0,0,0,0,0]$	$E^{a_1\cdots a_9}$

Table 1: *IIA Level decomposition of* $\mathfrak{e}_{10}$ *under* $\mathfrak{sl}(9,\mathbb{R})$.

the levels ℓ_1 and ℓ_2 are either both non-positive or both non-negative. In terms of the multilevel $\ell = (\ell_1, \ell_2)$ we shall denote this by $\ell \leq 0$ or $\ell \geq 0$, respectively. This implies that the level decomposition induces a grading of $\mathfrak{e}_{10}$ into an infinite set of finite-dimensional subspaces $\mathfrak{g}_\ell$ with respect to the multilevel ℓ. Let E_ℓ and $E_{\ell'}$ be arbitrary root vectors in the subspaces $\mathfrak{g}_\ell$ and $\mathfrak{g}_{\ell'}$ of $\mathfrak{e}_{10}$. Then a generic commutator, generalizing (3.11), takes the form

$$[E_\ell, E_{\ell'}] = E_{\ell+\ell'} \ \in \ \mathfrak{g}_{\ell+\ell'}. \tag{3.12}$$

The negative level generators are simply obtained using the Chevalley involution, and for an arbitrary positive level generator $E_\ell \in \mathfrak{g}_\ell$ we define the associated negative generator as

$$F_\ell := -\omega(E_\ell) \in \mathfrak{g}_{-\ell}, \qquad \ell \in \mathbb{Z}^2_{\geq 0}. \tag{3.13}$$

Because of the graded structure, commutators between generators in $\mathfrak{g}_\ell$ and $\mathfrak{g}_{-\ell}$ belong to the zeroth subspace $\mathfrak{g}_0$. For example, for the fundamental generator $E^{ab} \in \mathfrak{g}_{(0,1)}$ we have

$$[E^{a_1a_2}, F_{b_1b_2}] = -\frac{1}{2}\delta^{a_1a_2}_{b_1b_2}K + 4\delta^{[a_1}_{[b_1}K^{a_2]}{}_{b_2]} - 2\delta^{a_1a_2}_{b_1b_2}T. \tag{3.14}$$

The explicit form of the remaining commutators can be found in Appendix B.1.

3.2.2 The 'mass generator'

Let us now discuss in more detail how the generator associated with the mass term appears in the level decomposition of $\mathfrak{e}_{10}$. First consider the decomposition with respect to ℓ_1 (see Appendix E). At level $\ell_1 = 4$ one finds a generator corresponding to an $\mathfrak{sl}(10,\mathbb{R})$-tensor with 12 indices of the form $E^{\dot{a}|\dot{b}|\dot{c}_1\cdots\dot{c}_{10}}$ (with $\dot{a} = (10, a)$, etc.), which has mixed Young symmetry, i.e. it is antisymmetric in the block of indices $\dot{c}_1, \ldots, \dot{c}_{10}$ and symmetric in $\dot{a}, \dot{b}$. This generator has no physical interpretation in $D = 11$ supergravity. However, consider now the further level decomposition with respect to ℓ_2. This can be realized by doing a dimensional reduction on $E^{\dot{a}|\dot{b}|\dot{c}_1\cdots\dot{c}_{10}}$ along the direction '10'. We are interested in the generator obtained in this way by fixing the first three indices to $\dot{a} = \dot{b} = \dot{c}_1 = 10$, which yields [37, 54]

$$E^{a_1\cdots a_9} := \frac{1}{8} E^{10|10|10 a_1\cdots a_9}. \tag{3.15}$$

The resulting tensor corresponds to the $(\ell_1, \ell_2) = (4, 1)$-generator $E^{a_1\cdots a_9}$ in Table 1. This $\mathfrak{sl}(9, \mathbb{R})$-tensor is a nine-form, and is therefore associated with a supergravity potential $A_{a_1\cdots a_9}$ whose field-strength is a top-form in $D = 10$. This is the generator associated with the mass term. From this analysis it is clear that the mass deformation of type IIA supergravity probes $\mathfrak{e}_{10}$ beyond the realm of what has been successfully verified previously in the context of $D = 11$ supergravity. This is especially interesting due to the fact that the $\ell_1 = 4$-generator $E^{\dot{a}|\dot{b}|\dot{c}_1\cdots\dot{c}_{10}}$ is a 'genuine' $\mathfrak{e}_{10}$ element, with no components contained in $\mathfrak{e}_8$ nor in $\mathfrak{e}_9$.

3.2.3 Generators of $\mathfrak{k}(\mathfrak{e}_{10})$

The level decomposition of $\mathfrak{e}_{10}$ induces a decomposition of its maximal compact subalgebra $\mathfrak{k}(\mathfrak{e}_{10})$ which was defined in (3.3). Using the Cartan decomposition, (3.5) and (3.6), we define compact and noncompact generators, $J_\ell \in \mathfrak{k}(\mathfrak{e}_{10})$ and $S_\ell \in \mathfrak{p}$, as follows

$$J_\ell := E_\ell - F_\ell, \qquad S_\ell := E_\ell + F_\ell, \qquad \ell \in \mathbb{Z}^2_{\geq 0} \backslash \{(0, 0)\}. \tag{3.16}$$

Furthermore, at level $(0, 0)$ we have the $\mathfrak{so}(9)$ Lorentz generators

$$M^{ab} := K^a{}_b - K^b{}_a. \tag{3.17}$$

This decomposition of $\mathfrak{k}(\mathfrak{e}_{10})$ is not a gradation, but rather corresponds to a *filtration* [21], in the sense that an arbitrary commutator between two 'positive level' generators exhibits a graded structure modulo lower-level generators only,

$$[J_\ell, J_{\ell'}] = J_{|\ell-\ell'|} + J_{\ell+\ell'}, \tag{3.18}$$

where it is understood that $J_{|\ell-\ell'|} \neq 0$ if and only if $(\ell - \ell') \geq 0$ or $(\ell - \ell') \leq 0$. In other words, $J_{|\ell-\ell'|}$ is non-zero only when the difference $(\ell - \ell')$ involves no mixing between negative and positive levels.

Using (3.16), together with the $\mathfrak{e}_{10}$ commutators in Appendix B.1, we may deduce the abstract $\mathfrak{k}(\mathfrak{e}_{10})$-relations at each 'level'. Let us consider a few examples to illustrate the procedure. We begin by defining the $\mathfrak{k}(\mathfrak{e}_{10})$-generators associated with level $(0,0)$ and the fundamental generators at level $(0,1)$ and $(1,0)$:

$$J^a := E^a - F_a, \qquad J^{ab} := E^{ab} - F_{ab}. \tag{3.19}$$

Since there are no generators of mixed level $(1,-1)$ the commutator $[E^a, F_b]$ vanishes, and the commutator between J^{ab} and J^c simply gives

$$[J^{ab}, J^c] = J^{abc}, \tag{3.20}$$

with $J^{abc} := E^{abc} - F_{abc}$. Proceeding in the same way for $J^{a_1a_2}$ and $J^{a_1a_2a_3}$, we obtain $J^{a_1\cdots a_5}$ modulo lower level terms,

$$[J^{a_1a_2}, J^{a_3a_4a_5}] = J^{a_1\cdots a_5} - 6\delta^{[a_3a_4}_{a_1a_2}J^{a_5]}. \tag{3.21}$$

Note that one may project onto $J^{a_1\cdots a_5}$ as follows,

$$J^{a_1\cdots a_5} = \left[J^{[a_1a_2}, J^{a_3a_4a_5]}\right] . \tag{3.22}$$

Here, all indices are $\mathfrak{so}(9)$ vector indices and are raised and lowered with the Euclidean δ_{ab} so that the position does not matter. The other relevant $\mathfrak{k}(\mathfrak{e}_{10})$-commutators are listed in Appendix B.2.

3.3 Spinorial representations

The fermionic degrees of freedom in the sigma model for $E_{10}/K(E_{10})$ transform in spinorial representations of $\mathfrak{k}(\mathfrak{e}_{10})$. The two relevant $\mathfrak{k}(\mathfrak{e}_{10})$ representations are finite-dimensional (unfaithful) and of dimensions 32 and 320, respectively. In the decomposition of $\mathfrak{k}(\mathfrak{e}_{10})$ associated with eleven-dimensional supergravity these representations transform as a 32-dimensional Dirac spinor representation ϵ of $\mathfrak{so}(10) \subset \mathfrak{k}(\mathfrak{e}_{10})$ and a 320-dimensional vector-spinor representation $\Psi_{\dot{a}}$, $\dot{a} = (10, a)$, of $\mathfrak{so}(10) \subset \mathfrak{k}(\mathfrak{e}_{10})$, identified with the gravitino [17–19, 21]. Upon reduction to the IIA theory (through the additional level decomposition with respect to ℓ_2) the gravitino decomposes into a 32-dimensional spinor Ψ_{10} and a 288-dimensional vector spinor Ψ_a of $\mathfrak{so}(9)$. However, because they both descend from $\Psi_{\dot{a}}$, these two representations will mix under $\mathfrak{k}(\mathfrak{e}_{10})$ [20]. No such complication arises for the supersymmetry parameter ϵ, for which we keep the same notation in the IIA picture. The spinor Ψ_{10} will be associated with the ten-dimensional dilatino, while the vector-spinor Ψ_a is related to the gravitino.

For the first three levels, the transformation properties of the spinor ϵ are

$$\begin{aligned} M^{ab} \cdot \epsilon &= \frac{1}{2}\Gamma^{ab}\epsilon, \\ J^a \cdot \epsilon &= \frac{1}{2}\Gamma_{10}\Gamma^a\epsilon, \\ J^{ab} \cdot \epsilon &= \frac{1}{2}\Gamma_{10}\Gamma^{ab}\epsilon, \end{aligned} \tag{3.23}$$

where Γ^a and Γ^{ab} are $\mathfrak{so}(9)$ Γ-matrices (our Γ-matrix conventions are given in Appendix A.1). The higher level transformations are now defined through the abstract $\mathfrak{k}(\mathfrak{e}_{10})$-relations; for example:

$$\begin{aligned}
J^{a_1a_2a_3} \cdot \epsilon &:= \Big[J^{a_1a_2}, J^{a_3}\Big] \cdot \epsilon \qquad = \frac{1}{2}\Gamma^{a_1a_2a_3}\epsilon, \\
J^{a_1\cdots a_5} \cdot \epsilon &:= \Big[J^{[a_1a_2}, J^{a_3a_4a_5]}\Big] \cdot \epsilon = \frac{1}{2}\Gamma_{10}\Gamma^{a_1\cdots a_5}\epsilon.
\end{aligned} \tag{3.24}$$

Similarly, we have for the spinor component Ψ_{10} the following low-level transformations:

$$\begin{aligned}
M^{a_1a_2} \cdot \Psi_{10} &= \frac{1}{2}\Gamma^{a_1a_2}\Psi_{10} \\
J^{a} \cdot \Psi_{10} &= \frac{1}{2}\Gamma_{10}\Gamma^{a}\Psi_{10} + \Psi^{a}, \\
J^{a_1a_2} \cdot \Psi_{10} &= \frac{1}{6}\Gamma_{10}\Gamma^{a_1a_2}\Psi_{10} + \frac{4}{3}\Gamma^{[a_1}\Psi^{a_2]},
\end{aligned} \tag{3.25}$$

showing explicitly the mixing between Ψ_{10} and Ψ_a under $\mathfrak{k}(\mathfrak{e}_{10})$. Finally, we also have for Ψ_a:

$$\begin{aligned}
M^{a_1a_2} \cdot \Psi_{b} &= \frac{1}{2}\Gamma^{a_1a_2}\Psi_{b} + 2\delta_b^{[a_1}\Psi^{a_2]}, \\
J^{a} \cdot \Psi_{b} &= \frac{1}{2}\Gamma_{10}\Gamma^{a}\Psi_{b} - \delta_b^{a}\Psi_{10}, \\
J^{a_1a_2} \cdot \Psi_{b} &= \frac{1}{2}\Gamma_{10}\Gamma^{a_1a_2}\Psi_{b} - \frac{4}{3}\Gamma_{10}\delta_b^{[a_1}\Psi^{a_2]} + \frac{2}{3}\Gamma_{10}\Gamma_b{}^{[a_1}\Psi^{a_2]} \\
&\quad + \frac{4}{3}\delta_b^{[a_1}\Gamma^{a_2]}\Psi_{10} - \frac{1}{3}\Gamma_b{}^{a_1a_2}\Psi_{10}.
\end{aligned} \tag{3.26}$$

More details on these $\mathfrak{k}(\mathfrak{e}_{10})$-representations can be found in Appendix B.2. We note that we could also have redefined the $SO(9)$ spinor Ψ_a by a shift with $\Gamma_a\Gamma^{10}\Psi_{10}$ as one does in Kaluza–Klein reduction (cf. (A.18)) but refrain from doing so here.

3.4 The non-linear sigma model for $E_{10}/K(E_{10})$

A non-linear sigma model with rigid E_{10}-invariance and local $K(E_{10})$-invariance may now be constructed using the properties of $\mathfrak{e}_{10}$ described in previous sections. By virtue of the Iwasawa decomposition we can always choose a coset representative in the partial 'Borel gauge' by taking

$$\mathcal{V}(t) := \mathcal{V} = \mathcal{V}_0 e^{\phi T} e^{A\star E} \;\in\; E_{10}/K(E_{10}), \tag{3.27}$$

where $\mathcal{V}_0 = \exp\, h^a{}_b K^b{}_a$ represents the $GL(9,\mathbb{R})$ inverse vielbein $e_a{}^m$, while $e^{A\star E}$ contains the positive step operators of $\mathfrak{e}_{10}$. We call this a partial Borel gauge since $\mathcal{V}_0$ is not constrained to contain only positive step operators of $\mathfrak{gl}(9,\mathbb{R})$. In other words, $\mathcal{V}_0$ is an arbitrary $GL(9,\mathbb{R})$-matrix and not a representative of the coset $GL(9,\mathbb{R})/SO(9)$. With some abuse of terminology, we shall sometimes refer to the part of E_{10} parametrized by $\mathcal{V}$ as the 'Borel subgroup', and denote it by E_{10}^{+} [6]. The positive level part $e^{A\star E}$ of $\mathcal{V}$ is defined as

$$e^{A\star E} := \exp\big[A_m(t)E^m\big]\exp\big[\tfrac{1}{2}A_{m_1m_2}(t)E^{m_1m_2}\big]\exp\big[\tfrac{1}{3!}A_{m_1m_2m_3}(t)E^{m_1m_2m_3}\big]\cdots \tag{3.28}$$

with similar exponentials occurring for the higher levels. Note that in this expression the indices $m_1, m_2, \dots$ are $\mathfrak{sl}(9,\mathbb{R})$-indices, and hence correspond to curved spatial indices from a supergravity point of view.

The coset representative $\mathcal{V}$ transforms under global $g \in E_{10}$-transformations from the right and local $k \in K(E_{10})$-transformations from the left:

$$\mathcal{V} \longmapsto k\mathcal{V}g. \tag{3.29}$$

From $\mathcal{V}$ we construct the Lie algebra-valued Maurer–Cartan form

$$\partial_t\mathcal{V}\mathcal{V}^{-1} = \mathcal{P} + \mathcal{Q}, \tag{3.30}$$

where we also employed the Cartan decomposition, according to (3.6). The transformation property of $\mathcal{V}$ in (3.29) implies that the coset part $\mathcal{P} \in \mathfrak{p}$ of the Maurer-Cartan form is globally E_{10}-invariant while transforms covariantly under $K(E_{10})$:

$$K(E_{10}) \;:\; \mathcal{P} \;\longmapsto\; k\mathcal{P}k^{-1}. \tag{3.31}$$

On the other hand, $\mathcal{Q} \in \mathfrak{k}(\mathfrak{e}_{10})$ properly transforms as a connection,

$$K(E_{10}) \;:\; \mathcal{Q} \;\longmapsto\; k\mathcal{Q}k^{-1} + \partial_t k k^{-1}. \tag{3.32}$$

Using the bilinear form on $\mathfrak{e}_{10}$, we can now construct a manifestly $E_{10} \times K(E_{10})_{\text{local}}$-invariant Lagrangian as follows [8, 15]

$$\mathcal{L}^{[B]}_{E_{10}/K(E_{10})} = \frac{1}{4}n(t)^{-1}\left\langle \mathcal{P}\middle|\mathcal{P}\right\rangle, \tag{3.33}$$

where the lapse function $n(t)$ ensures invariance under reparametrizations of the geodesic parameter t. We have also included a superscript $[B]$ to emphasize that this Lagrangian is only the bosonic part of a sigma model which also includes the fermionic degrees of freedom in the **320** of $K(E_{10})$ to be introduced shortly. The equations of motion for $n(t)$ enforces a lightlike (Hamiltonian) constraint on the dynamics,

$$\left\langle \mathcal{P}\middle|\mathcal{P}\right\rangle = 0, \tag{3.34}$$

---

[6] This differs from the 'true' Borel subgroup $B := \exp\,\mathfrak{b} \subset E_{10}$ through the negative root generators in $\mathcal{V}_0$ (see Section 3.1 for the definition of $\mathfrak{b}$). E_{10}^{+} is only a parabolic subgroup of E_{10}.

while the equations of motion for $\mathcal{P}$ (in the gauge $n = 1$) read

$$\mathcal{D}\mathcal{P} := \partial_t \mathcal{P} - [\mathcal{Q}, \mathcal{P}] = 0, \tag{3.35}$$

where we defined the $K(E_{10})$-covariant derivative $\mathcal{D}$. Equation (3.35) encodes the dynamics of the bosonic sector of the sigma model and is written out in detail in Appendix C.1.

The fermionic degrees of freedom are included in the Lagrangian through the spinor representation Ψ as follows [18, 19, 21]

$$\mathcal{L}^{[F]}_{E_{10}/K(E_{10})} = -\frac{i}{2} \left\langle \Psi \middle| \mathcal{D}\Psi \right\rangle, \tag{3.36}$$

where the bracket now denotes an invariant inner product on the representation space. The associated 'Dirac equation' reads

$$\mathcal{D}\Psi := \partial_t \Psi - \mathcal{Q} \cdot \Psi = 0, \tag{3.37}$$

where it is understood that the connection $\mathcal{Q}$ acts on Ψ in the vector-spinor representation constructed in the previous section. Equation (3.37) is written in terms of the full 320-dimensional spinor Ψ, which encodes both the 'gravitino' Ψ_a and the 'dilatino' Ψ_{10}. The separate equations of motion for these fields can be written out as follows

$$\begin{aligned} \mathcal{D}\Psi_a &:= \partial_t \Psi_a - \mathcal{Q} \cdot \Psi_a = 0, \\ \mathcal{D}\Psi_{10} &:= \partial_t \Psi_{10} - \mathcal{Q} \cdot \Psi_{10} = 0. \end{aligned} \tag{3.38}$$

Recall that the $\mathfrak{k}(\mathfrak{e}_{10})$-action on Ψ_a contains Ψ_{10}-terms, and vice versa. This is important since the same mixing between the gravitino and the dilatino occurs in the corresponding supergravity equations of motion (see Appendix A.4). The fermionic equations of motion in (3.38) are written out in more detail in Appendix C.2.

The bosonic equations of motion (3.35) were written for the gauge choice $n = 1$. The lapse function n has a superpartner Ψ_t, which is a Dirac spinor under $\mathfrak{k}(\mathfrak{e}_{10})$, and the associated supersymmetry transformations are

$$\begin{aligned} \delta_\epsilon n &= i\epsilon^T \Psi_t, \\ \delta_\epsilon \Psi_t &= \mathcal{D}\epsilon. \end{aligned} \tag{3.39}$$

The fermionic equations of motion are then valid in the 'supersymmetric gauge' $\Psi_t = 0$. The associated constraint (analogous to the Hamiltonian constraint) that should be imposed is the supersymmetry constraint which states that the spin Ψ is orthogonal to the velocity $\mathcal{P}$. The full form of this constraint is unknown due to the fact that it is not known how to supersymmetrize the E_{10} model correctly. Nevertheless, low level expressions have been obtained in [18,21], which the reader should also consult for further discussions of this point. Certain aspects of the supersymmetry constraint are also discussed in Section 5.2.

Let us now analyse these properties of the geodesic sigma model in more detail by utilizing the level decomposition of $\mathfrak{e}_{10}$ with respect to $\mathfrak{sl}(9,\mathbb{R})$. Expanding the coset element $\mathcal{P}$ up to level $(3,2)$ we obtain

$$\mathcal{P} \;=\; \partial_t\phi T + \frac{1}{2}p_{ab}(K^a{}_b + K^b{}_a) + \sum_{\ell>0} P_\ell \star S_\ell \tag{3.40}$$

and the associated expansion for $\mathcal{Q}$ is given by

$$\mathcal{Q} = \frac{1}{2}q_{ab}M^{ab} + \sum_{\ell>0} Q_\ell \star J_\ell, \tag{3.41}$$

where $\star$ schematically denotes the coupling between the dynamical fields P_ℓ and the associated generators S_ℓ. The explicit form of this expansion will be given below. In Borel gauge, the fields at non-zero levels are the same in $\mathcal{Q}$ and $\mathcal{P}$:

$$Q_\ell \equiv P_\ell, \qquad \ell \in \mathbb{Z}^2_{\geq 0}\backslash\{(0,0)\}\,. \tag{3.42}$$

The explicit form of the higher level terms in the expansion of $\mathcal{P}$ reads

$$\begin{aligned}\sum_{\ell>0} P_\ell \star S_\ell \;:=\;& e^{3\phi/4}P_{a_1}S^{a_1} + \frac{1}{2}e^{-\phi/2}P_{a_1a_2}S^{a_1a_2} + \frac{1}{3!}e^{\phi/4}P_{a_1a_2a_3}S^{a_1a_2a_3}\\ &+\frac{1}{5!}e^{-\phi/4}P_{a_1\ldots a_5}S^{a_1\ldots a_5} + \frac{1}{6!}e^{\phi/2}P_{a_1\ldots a_6}S^{a_1\ldots a_6} + \frac{1}{7!}e^{-3\phi/4}P_{a_1\ldots a_7}S^{a_1\ldots a_7}\\ &+\frac{1}{8!}P_{a_1\ldots a_8}S^{a_1\ldots a_8} + \frac{1}{8!}P_{a_0|a_1\ldots a_7}S^{a_0|a_1\ldots a_7} + \frac{1}{9!}e^{-5\phi/4}P_{a_1\ldots a_9}S^{a_1\ldots a_9} + \ldots\end{aligned} \tag{3.43}$$

with a similar expression for $\mathcal{Q}$ with the S_ℓ's replaced by the corresponding J_ℓ's.

From a given parametrization of $\mathcal{V}$ as in (3.28) one can work out explicit expressions for $\mathcal{P}$ in terms of the 'potentials' A_ℓ (which *a fortiori* carries flat indices as it transforms under $\mathfrak{k}(\mathfrak{e}_{10})$) which appear in the construction of $\mathcal{V}$. For example, one finds

$$P_a = \frac{1}{2}e_a{}^m\partial_t A_m = \frac{1}{2}e_a{}^m DA_m \tag{3.44}$$

in terms of the 'covariant derivatives' of [8]. Here, we have written $\mathcal{V}_0 = e_a{}^m$ as an inverse $GL(9,\mathbb{R})$ vielbein. We do not require the exact expressions for the higher level components of $\mathcal{P}$ for establishing the correspondence and their expression will be more complicated due to the appearance of additional terms, arising when expanding the Maurer-Cartan form $\partial_t\mathcal{V}\mathcal{V}^{-1}$ using the Baker–Campbell–Hausdorff formula $de^Xe^{-X} = dX + \frac{1}{2}[X,dX] + \ldots$. In Section 5 when we discuss constraints and aspects of gauge-fixing the precise form will be more relevant and we will give more details there.

The geodesic equations $\partial_t\mathcal{P} = [\mathcal{Q},\mathcal{P}]$ can be written conveniently by treating the $\mathcal{V}_0$ contribution separately in a partially covariant derivative $D^{(0)}$, see [15]. For example, for the fundamental generators at level $(0,1)$ and $(1,0)$ the equations of motion become (for $n=1$)

$$\begin{aligned} D^{(0)}(e^{3\phi/2}P_a) &= -e^{\phi/2}P_{ac_1c_2}P_{c_1c_2} + \frac{2}{5!}e^{\phi}P_{ac_1\ldots c_5}P_{c_1\ldots c_5} + \frac{12}{8!}P_{ac_1\ldots c_7}P_{c_1\ldots c_7} \\ &\quad + \frac{1}{4\cdot 7!}P_{a|c_1\ldots c_7}P_{c_1\ldots c_7} \end{aligned} \tag{3.45}$$

$$\begin{aligned} D^{(0)}(e^{-\phi}P_{a_1a_2}) &= 2e^{\phi/2}P_{a_1a_2c}P_c + \frac{1}{3}e^{-\phi/2}P_{a_1a_2c_1c_2c_3}P_{c_1c_2c_3} \\ &\quad + \frac{2}{5!}e^{-3\phi/2}P_{a_1a_2c_1\ldots c_5}P_{c_1\ldots c_5} + \frac{2}{7!}e^{-5\phi/2}P_{a_1a_2c_1\ldots c_7}P_{c_1\ldots c_7} \\ &\quad + \frac{1}{6!}P_{a_1a_2c_1\ldots c_6}P_{c_1\ldots c_6} + \frac{1}{4\cdot 5!}P_{c_1|c_2\ldots c_6a_1a_2}P_{c_1\ldots c_6}. \end{aligned} \tag{3.46}$$

In Section 4 we will show that these equations are equivalent to the equations of motion for the electric fields F_{ta} and F_{tab}, respectively. The equations for all the remaining levels are given in Appendix C.1. The fermionic equations of motion can be found in C.2 where the connection term $\mathcal{Q}$ is evaluated in the vector-spinor representation. The supersymmetry variation (3.39) requires the evaluation of $\mathcal{Q}$ in the Dirac-spinor representation, the resulting expression can be found in C.3.

4 The correspondence

In this section we make the E_{10}/massive IIA correspondence explicit by giving a dictionary between the dynamical variables of the $E_{10}/K(E_{10})$-sigma model and the fields of massive IIA supergravity. The comparison cannot be done at the level of the respective Lagrangians since the E_{10} sigma model naturally incorporates kinetic terms for all fields as well as their duals, which is not the case for the IIA Lagrangian. The matching is rather done at the level of the equations of motion, where we will see that bosonic equations of motion and Bianchi identities on the supergravity side all become associated with geodesic equations of motion on the E_{10} side. Similarly, the fermionic supergravity equations will be associated with the Dirac equation of the spinning coset particle.

4.1 Bosonic equations of motion and truncation

To be able to compare the equations of motion on the supergravity side (A.5) and (A.6) to the ones on the sigma model side (3.35), spelt out in Appendix C.1, we need to rewrite the former. As is customary in the correspondence between E_{10} and supergravity we split the indices $\alpha=(0,a)$ into temporal and spatial indices and also adopt a pseudo-Gaussian gauge for the ten-dimensional vielbein:

$$e_\mu{}^\alpha = \begin{pmatrix} N & 0 \\ 0 & e_m{}^a \end{pmatrix}. \tag{4.1}$$

In addition we demand that the spatial trace of the spin connection vanishes (see Appendix A.1 for our conventions)

$$\omega_{a\,ab} = 0 \quad \Rightarrow \quad \Omega_{ba\,a} = 0 \tag{4.2}$$

and write the tracefree spin connection as $\tilde{\omega}_{a\,bc}$ as a reminder. We also choose temporal gauges for all supergravity gauge potentials,

$$A_t = 0\,, \quad A_{tm} = 0\,, \quad A_{tm_1m_2} = 0\,. \tag{4.3}$$

Moreover, we can only expect that a truncated version of the supergravity equation corresponds to the coset model equations. This truncation was originally devised in the context of eleven-dimensional supergravity, where it was strongly motivated by the billiard analysis of the theory close to a spacelike singularity (the 'BKL-limit') [8, 15]. In this limit, spatial points decouple and the dynamics becomes effectively time-dependent, ensuring that the truncation is a valid one in this regime. In this paper, we analyse the same question in the context of massive IIA supergravity, and an identical procedure requires the truncation of a set of spatial gradients. These can be obtained from a BKL-type analysis of massive IIA and their full list is presented in Appendix A.5. Notice that except for the expression involving the mass, all the spatial gradients to be truncated away can be obtained by dimensional reduction of the eleven-dimensional truncation.

Let us illustrate the implications of this truncation on the supergravity equations in some detail for an explicit example. The following truncation of massive IIA supergravity can be deduced from the billiard analysis:

$$\partial_a \left(N e^{3\phi/4} F_{b_1 b_2} \right) = 0. \tag{4.4}$$

The effect of this truncation appears in the equation of motion for the two-form field strength $F_{\alpha\beta}$ (see (A.5a) in Appendix A.3). After splitting time and space indices, the space component of this equation reads[7]

$$\begin{aligned} D^{(0)}(e^{3\phi/2}F_{tb}) &= -\frac{1}{2}e^{\phi/2}F_{ta_1a_2b}F_{ta_1a_2} + \frac{1}{3!}e^{\phi/2}N^2 F_{a_1\ldots a_3 b}F_{a_1\ldots a_3} \\ &\quad + \frac{3}{4}e^{3\phi/2}N^2\partial_a\phi F_{ab} - \frac{1}{2}e^{3\phi/2}N^2\Omega_{a_1a_2b}F_{a_1a_2} \\ &\quad + N e^{3\phi/4}\partial_a\left(N e^{3\phi/4}F_{ab}\right)\,. \end{aligned} \tag{4.5}$$

Using the truncation (4.4), the last term on the right hand side vanishes, and consequently the equation to compare with the E_{10} equation of motion (3.45) is (4.5) without the bottom

---

[7] $D^{(0)}$ here contains the contributions from the time derivatives of the spatial vielbein $e_m{}^a$ and will be identified with the corresponding E_{10} coset derivative operator below.

(ℓ_1, ℓ_2)	E_{10} fields	Bosonic fields of supergravity

Table 2: *Bosonic dictionary: This table shows the correspondence between E_{10} fields and bosonic fields of massive IIA supergravity that one obtains by considering the equations of motion and the Bianchi equations.*

line. Let us emphasize that the truncation (4.4) also follows from dimensional reduction of the associated truncation in the equation of motion for the electric field $F_{0\dot{a}_1\dot{a}_2\dot{a}_3}$ in eleven dimensions [8, 15]. Moreover, this example makes clear the important comment that the truncation we impose is *not* equivalent to discarding all spatial gradients on the supergravity side, since it is clear that spatial derivatives of the one-form potential A_a are implicitly contained in $F_{a_1a_2}$.

From comparing in detail the supergravity equations (Appendix A) with the truncations applied with the bosonic equations of the coset model (Appendix C.1) one can derive a correspondence between the components of the coset velocity $\mathcal{P}$ and the fields of supergravity. The dictionary is given in Table 2 where, in the last line, $e = \det\, e_m{}^a = \sqrt{\det\, g_{mn}} = \sqrt{g}$. It is perfectly consistent with identifying the form equations of motion (A.5) with the sigma model expressions (C.2a) to (C.2c), the Bianchi identities (A.4) with the equations (C.2d) to (C.2g) and the dilaton equation of motion (A.6a) with (C.1a).

The remaining equation, the Einstein equation (A.6b), does not fit perfectly in this picture. More precisely, two terms do not match completely with (C.1b). One is similar to the mismatch in the A_9 decomposition relevant to $D = 11$ supergravity and is a contribution to the Ricci tensor R_{ab} of the form $\Omega_{a\,cd}\Omega_{b\,dc}$ [15]. The other term is a mismatch of the coefficient in the energy momentum tensor of the dilaton $T_{ab} \sim \partial_a\phi\partial_b\phi$; the coefficient is off by a factor two. This can be traced back to $D = 11$ where both mismatches were part of the $D = 11$ Ricci tensor. In this sense this is not a new discrepancy but a known one. It is to be noted that all the terms involved in the mismatch are related to contributions to the Lagrangian which would give rise to walls corresponding to imaginary roots in the cosmological billiards picture [8]. There is no mismatch in the equation of motion of the dilaton ϕ since in the reduction the missing term in $D = 11$ does not contribute to this equation.

Let us study the effect of the mass term more closely. In the bosonic equations, the mass appears in five places: the dilaton equation (A.6a), the Einstein equation (A.6b), the equation of motion for $F_{ta_1a_2}$ (A.5b), the Bianchi equation for $F_{a_1a_2}$ (A.4a) and of course in its own equation of motion $\partial_t m = 0$. It is remarkable that the contribution of the real root corresponding to the mass deformation enters all equivalent sigma-model equations correctly, even though it is beyond the realm of E_8 generators and above height 30. In particular, the E_{10}-invariant sigma model produces the right potential for the scalar ϕ. This is possible since the supergravity potential is positive definite in agreement with positive definiteness of the E_{10}-invariant Lagrangian (3.33) away from the Cartan subalgebra. By contrast, for gauged deformations in lower dimensions where the supergravity potential is indefinite and not reproduced fully by E_{10} [33]. From this point of view the massive Romans theory seems to be special since the E_{10} model reproduces correctly all the effects of the deformation.

4.2 The truncation revisited

The truncation we applied to supergravity, using billiard arguments, also proves useful for ensuring the consistency of the dictionary. Indeed, notice that all the sigma model variables depend on (sigma model) ‘time’ only, and hence we must demand that their spatial gradients vanish:

$$\partial_a \mathcal{P}(t) = 0. \tag{4.6}$$

Applied to the Maurer–Cartan expansion, this equation translates to constraints on the supergravity variables upon using the dictionary in Table 2. Of course, (4.6) does not really make sense on the sigma model side, where spatial gradients have no meaning, but must rather be understood as a convenient way of encoding the relevant truncations on the supergravity side. Nevertheless, the truncations encoded in (4.6) correspond precisely to the truncations we have just imposed. Let us illustrate this for the example of the truncation on the magnetic field in (4.5). The level $(3, 1)$ part of the expansion of the Maurer-Cartan form contains the following term (see (3.43))

$$\mathcal{P}(t)\big|_{(3,1)} = \frac{1}{7!}e^{-3\phi/4}P_{a_1\cdots a_7}(t)S^{a_1\cdots a_7}. \tag{4.7}$$

The coefficient of the generator $S^{a_1\cdots a_7} \in \mathfrak{e}_{10}$ is a dynamical quantity which is purely time-dependent. This implies that on the supergravity side we must make sure that the corresponding quantity is also purely time-dependent, i.e. we must demand

$$\partial_a(e^{-3\phi/4}P_{a_1\cdots a_7}) = 0, \tag{4.8}$$

which, after using the dictionary in Table 2, precisely yields the truncation in (4.4). Similarly, one sees that requiring (4.6) for each term of the Maurer-Cartan expansion corresponds to the truncations of Appendix A.5.

4.3 Fermionic equations of motion

To make contact between the fermionic equations of Romans' theory, (equations of motion (A.7) and (A.11) and supersymmetry variation (2.4)), and the Kac-Moody side of the story, (equations of motion (C.3) and (C.4) and supersymmetry variation (C.5)), we must make some further field redefinitions. We redefine the gravitino components, the dilatino and the supersymmetry parameter as

$$\begin{aligned}
\tilde{\psi}_0 &\equiv g^{1/4}\Big(\psi_0 - \Gamma_0\Gamma^a\psi_a\Big),\\
\tilde{\psi}_a &\equiv g^{1/4}\Big(\psi_a - \frac{1}{12}\Gamma_a\lambda\Big),\\
\tilde{\lambda} &\equiv \frac{2}{3}g^{1/4}\lambda,\\
\tilde{\varepsilon} &\equiv g^{-1/4}\varepsilon.
\end{aligned} \tag{4.9}$$

With these redefinitions, using the bosonic dictionary obtained in the previous section and in the gauge

$$\tilde{\psi}_0 = 0, \tag{4.10}$$

we can show that the equations of motion of the fermions of massive IIA supergravity (A.7) and (A.11) are equivalent to the Kac-Moody fermionic spinor equations (C.3) and (C.4) if we assume a correspondence between the unfaithful representation of $\mathfrak{k}(\mathfrak{e}_{10})$ and the redefined fermionic fields displayed in the first half of Table 3.

To illustrate how the correspondence is proved, let us consider the mass terms of the equation of motion for the gravitino. On the supergravity side, one looks at the spatial components of the equation of motion (A.11). We only keep the terms involving the time derivative of ψ_a and the mass:

$$\partial_0\psi_a + \frac{1}{16}e^{5\phi/4}m\Gamma^0\Gamma_{ab}\psi^b + \frac{5}{16}e^{5\phi/4}m\Gamma^0\psi_a + \frac{5}{64}e^{5\phi/4}m\Gamma^0\Gamma_a\lambda + \cdots = 0. \tag{4.11}$$

$K(E_{10})$ representations	Fermionic fields of supergravity
Ψ_a	$\tilde{\psi}_a = g^{1/4}\Big(\psi_a - \frac{1}{12}\Gamma_a\lambda\Big)$
$\Gamma^{10}\Psi_{10}$	$\tilde{\lambda} = \frac{2}{3}g^{1/4}\lambda$
ϵ	$\tilde{\varepsilon} = g^{-1/4}\varepsilon$
Ψ_t	$\tilde{\psi}_t = ng^{1/4}\Big(\psi_0 - \Gamma_0\Gamma^a\psi_a\Big)$

Table 3: *Fermionic dictionary: This table presents the relation between the spinor and vector spinor unfaithful representations of* $\mathfrak{k}(\mathfrak{e}_{10})$ *and the fermionic fields of massive type IIA supergravity. The first half is obtained by requiring the equations of motion for the fermions to match with the* $\mathfrak{k}(\mathfrak{e}_{10})$ *equation and the second half comes from the supersymmetry variation of* ψ_t.

One the sigma model side, we must consider the terms at level $(4,1)$ of the explicit version of the equation of motion (C.4), that give

$$\partial_t\Psi_a - \frac{1}{2\cdot 9!}e^{-5\phi/4}P_{b_1\cdots b_9}\Gamma_{10}\Gamma^{b_1\cdots b_9}\Psi_a + \frac{12}{9!}e^{-5\phi/4}P_{b_1\cdots b_9}\Gamma_{10}\Gamma_a{}^{b_1\cdots b_8}\Psi^{b_9} + \cdots = 0. \quad (4.12)$$

Using the bosonic and fermionic dictionaries given in Tables 2 and 3, it is now a purely algebraic exercise to see that (4.11) and (4.12) are equivalent.

4.4 Supersymmetry variations of fermions

Considering the supersymmetry variation of the gravitino provides us with a consistency check of the previously obtained bosonic and fermionic dictionaries. To this end it is natural to define

$$\tilde{\psi}_t \equiv n\tilde{\psi}_0, \quad (4.13)$$

where t is considered as a 'vector index' along the world line with respect to the einbein n.

Using the previous redefinitions yields the following supersymmetry transformation on the redefined gravitino

$$\begin{aligned}\delta_\varepsilon\tilde{\psi}_t \;=\;& \partial_t\varepsilon + \frac{1}{4}g^{-1}\partial_t g\varepsilon + \frac{1}{4}N\omega_{0ab}\Gamma^{ab}\varepsilon + \frac{1}{4}Ne^{5\phi/4}m\Gamma_0\varepsilon\\ &+\frac{1}{4\cdot 4!}e^{\phi/4}N\Gamma^{abcd}\Gamma_0F_{abcd}\varepsilon - \frac{1}{4\cdot 3!}e^{\phi/4}N\Gamma^{abc}F_{0abc}\varepsilon\\ &-\frac{1}{8}e^{3\phi/4}N\Gamma^{ab}\Gamma_0\Gamma_{10}F_{ab}\varepsilon + \frac{1}{4}e^{3\phi/4}N\Gamma^a\Gamma_{10}F_{0a}\varepsilon\\ &-\frac{1}{24}e^{-\phi/2}N\Gamma^{abc}\Gamma_0\Gamma_{10}F_{abc}\varepsilon - \frac{1}{8}e^{-\phi/2}N\Gamma^{ab}\Gamma_{10}F_{0ab}\varepsilon\\ &+\frac{1}{4}N\omega_{abc}\Gamma^{abc}\Gamma_0\varepsilon - N\Gamma_0\Gamma^a\Big[\partial_a\varepsilon + \frac{1}{4}g^{-1}\partial_a g\varepsilon\Big]. \end{aligned} \quad (4.14)$$

We can now identify the right hand side of (4.14) with the $K(E_{10})$-covariant derivative acting on the 32-dimensional spinor representation ϵ (3.39), given explicitly in (C.5), using the bosonic and fermionic dictionaries already computed (Tables 2 and 3). We then obtain the second half of Table 3, that is, the relations for the supersymmetry parameter and the time component of the gravitino.

In conclusion, we see that all the fermionic equations of motion as well as the supersymmetry variation of ψ_t match with the $E_{10}/K(E_{10})$ fermionic theory. In particular, we notice that the mass enters these equations correctly everywhere.

5 Gauge algebra and supersymmetry variations from E_{10}

In this section we address and collect a few general points which are of relevance for the analysis of hyperbolic Kac–Moody coset models in relation to deformed or undeformed supergravity. In particular, we point out some crucial features related to gauge-fixing in the E_{10} sigma model, and we discuss the associated constraints. We also show how the gauge algebra and supersymmetry variations of massive IIA supergravity may be obtained in a simple way from properties of E_{10} and $K(E_{10})$.

5.1 The importance of being gauge-fixed

As has been pointed out in [56], in order to reveal the correspondence between the geodesic equation of the sigma model and the equations of motion of supergravity it is essential that one fixes all gauges on both sides. For E_{10} this means that one should work in Borel gauge, whereas the supergravity variables are subject to the pseudo-Gaussian gauge (4.1) for the metric and also to temporal gauges for the p-form gauge fields (4.3) which are of particular importance in the context of the mass deformed supergravity theory.[8] The dictionary as stated was a correspondence at the level of the 'velocities', i.e. first derivatives of the basic variables. In the undeformed case, this correspondence also holds for the basic variables so that the coordinates parametrising the $E_{10}/K(E_{10})$ coset (in triangular gauge) can be identified with the (gauge-fixed) variables of supergravity [8]. For example, in massless IIA one would write a coset element[9]

$$\mathcal{V} = \mathcal{V}_0 e^{\phi T} e^{A_m E^m} e^{\frac{1}{2} A_{m_1 m_2} E^{m_1 m_2}} e^{\frac{1}{3!} A_{m_1 m_2 m_3} E^{m_1 m_2 m_3}} \cdots , \tag{5.1}$$

---

[8] The same phenomenon occurs for gauged supergravity [33].

[9] There is some ambiguity in parametrising the positive step operators which is directly related to possible field redefinitions in supergravity.

for which the Maurer–Cartan form (3.30) expands to (using $\mathcal{V}_0 = e_a{}^m$ as follows from Table 2)

$$\begin{aligned}\partial_t\mathcal{V}\,\mathcal{V}^{-1} \;&=\; -e_a{}^m\partial_t e_m{}^b K^a{}_b + \partial_\phi T + e^{3\phi/4}e_a{}^m\partial_t A_m E^a + \frac{1}{2}e^{-\phi/2}e_{a_1}{}^{m_1}e_{a_2}{}^{m_2}\partial_t A_{m_1m_2}E^{a_1a_2}\\ &\quad+\frac{1}{3!}e^{\phi/4}e_{a_1}{}^{m_1}e_{a_2}{}^{m_2}e_{a_3}{}^{m_3}(\partial_t A_{m_1m_2m_3} - 3A_{m_1}\partial_t A_{m_2m_3})E^{a_1a_2a_3} + \ldots\,.\end{aligned} \tag{5.2}$$

The fact that the coefficient of $E^{a_1a_2a_3}$ has several contributions is due to the expansion when using the Baker–Campbell–Hausdorff formula. As we are in Borel gauge this expansion is always guaranteed to terminate. The level zero pieces merely 'dress' the coefficients; $\mathcal{V}_0$ is the inverse vielbein $e_a{}^m$ from supergravity and converts curved into flat indices while $e^{\phi T}$ introduces a level dependent dilaton prefactor. The precise form of the extra terms in the coefficients of the generators E_ℓ in the Maurer-Cartan form is prescribed by the E_{10} structure and the parametrization chosen. Clearly, writing out the corresponding field strength $F_{tm_1m_2m_3}$ (see (2.2)) for vanishing mass gives in temporal gauge

$$F_{tm_1m_2m_3} = \partial_t A_{m_1m_2m_3} - 3A_{m_1}\partial_t A_{m_2m_3}\,, \tag{5.3}$$

which is exactly the coefficient of $E^{a_1a_2a_3}$ if the dilaton is extracted. Therefore the structure constants of E_{10} naturally encode the modified field strengths of supergravity, including Chern-Simons terms as well as extra terms involving lower-rank p-form potentials as in (5.3). Therefore we can, in more refined version of the dictionary in Table 2, identify the supergravity fields with the fields appearing in the parametrization of $\mathcal{V}$.

Continuing to the massive case $m \neq 0$ this logic seems to run into problems since there one has, for example,

$$F_{tn} = \partial_t A_n + mA_{tn}\,. \tag{5.4}$$

The mass term was identified with the time derivative of the nine-form potential appearing in the parametrisation of $E_{10}/K(E_{10})$ in Borel gauge. Such a term cannot arise from the Maurer-Cartan form since in Borel gauge the commutators in the expansion only increase the level, so that a coefficient of a generator on a given level has only contributions from lower-lying generators. Here, the gauge fixing (4.3) becomes important because it eliminates the second term in (5.4) by simply setting $A_{tn} = 0$. Hence, one can still identify the coset coordinate A_m with the supergravity gauge potential A_m even in the deformed case as long as one works in a completely gauge-fixed framework.[10]

---

[10] This is in contrast to the analysis of [35], where an additional (-1)-form generator was introduced in the algebra in the form of a translation generator. With such a generator the commutators are not only increasing in level; a similar logic was followed in [24, 26]. Formal (-1)-forms also appear in [47].

5.2 Constraints on the geodesic sigma model

Whenever gauges are fixed one has to remember to also impose the corresponding constraints. In the context of $\mathfrak{e}_{10}$ it has been observed in the $\mathfrak{sl}(10,\mathbb{R})$ decomposition that the constraints can be imposed consistently on the geodesic [16]. However, the constraints transform only under a Borel subgroup $E_{10}^{+} \subset E_{10}$; the relevant linear representation can be embedded into the highest weight representation $L(\Lambda_1)$ of $\mathfrak{e}_{10}$ and its low level content in the $\mathfrak{sl}(9,\mathbb{R})$ decomposition used in this paper is displayed in table 4.[11] $L(\Lambda_1)$ here indicates that the highest weight of this integrable $\mathfrak{e}_{10}$ representation has its weight given by the fundamental weight dual to the simple root of node 1. We note that the corresponding representation $L(\Lambda_1)$ of $\mathfrak{e}_{11}$ has been considered before both for the construction of space-time [57] and the construction of deformed supergravities [24, 26].

In the context of E_{10} one has to take into account the constraints that arise from fixing the pseudo-Gaussian gauge (4.1) for the vielbein and the temporal gauges (4.3) for the vector potentials. The vanishing shift component in the vielbein gives rise to the spatial diffeomorphism constraint, sometimes also called the momentum constraint. Fixing temporal gauge for a p-form potential one obtains an associated Gauss constraint which carries $(p-1)$ antisymmetric indices. Furthermore, there are Bianchi-type constraints associated with all fields which arise from the split between space and time. The details of the general construction can be found in [16], here we work out the details only for the case of the constraint on the mass parameter. The other constraints follow from the analysis of [16] by dimensional reduction.

It turns out to be more convenient to think of the supergravity Bianchi constraint on the mass parameter m as the Gauss constraint for a nine-form potential with ten-form field strength. In fact, all Bianchi constraints are secretly Gauss constraints of the dual variables in temporal gauge. In this case it is of the form

$$\partial_\mu \left(\sqrt{-G} e^{-5\phi/2} F^{\mu m_1 \dots m_8 t} \right) = 0\,, \tag{5.5}$$

where as usual one index was chosen to be t in order to obtain the Gauss constraint. This constraint also transforms manifestly as an eight-form, just like the contraint listed on level $(7,3)$ in Table 4.

We now turn to the corresponding constraint on the E_{10} side. In the general construction of the constraints [16], a constraint on level (ℓ_1, ℓ_2) is composed out of a product of two

---

[11] Except for the momentum constraint there are 'trailing' $\epsilon^{b_1 \cdots b_9}$ factors which have been suppressed in the table. They are not seen by $\mathfrak{sl}(9,\mathbb{R})$ but by $\mathfrak{gl}(9,\mathbb{R})$ and they correspond to volume factors, so that the corresponding 'tensors' transform as densities rather than true tensors. Their number can easily be recovered from demanding that the total number of indices on level (ℓ_1, ℓ_2) be $2\ell_1 + \ell_2$. Furthermore, there is a factor $\exp[(-2\ell_1 + 3\ell_2)\phi/4]$ of the dilaton will multiply the product of Ps in our conventions. We will exemplify this below.

(ℓ_1, ℓ_2)	$\mathfrak{sl}(9,\mathbb{R})$ Dynkin labels	Constraint
$(3,2)$	$[1,0,0,0,0,0,0,0]$	Momentum constraint
$(3,3)$	$[0,0,0,0,0,0,0,0]$	Gauss for A_a
$(4,2)$	$[0,0,0,0,0,0,0,1]$	Gauss for $A_{a_1 a_2}$
$(4,3)$	$[0,0,0,0,0,0,1,0]$	Gauss for $A_{a_1 a_2 a_3}$
$(5,3)$	$[0,0,0,0,1,0,0,0]$	Bianchi for $A_{a_1 a_2 a_3}$
$(5,4)$	$[0,0,0,1,0,0,0,0]$	Bianchi for $A_{a_1 a_2}$
$(6,3)$	$[0,0,1,0,0,0,0,0]$	Bianchi for A_a
$(6,4)$	$[0,1,0,0,0,0,0,0]$	Bianchi for ϕ
$(6,4)$	$[0,0,1,0,0,0,0,1] \oplus [0,1,0,0,0,0,0,0]$	Bianchi for Riemann
$(7,3)$	$[1,0,0,0,0,0,0,0]$	Bianchi for mass

Table 4: *IIA Level decomposition of $L(\Lambda_1)$ representation of $\mathfrak{e}_{10}$ under $\mathfrak{sl}(9,\mathbb{R})$.*

components P of the Cartan form (3.43) such that their levels add up to (ℓ_1, ℓ_2). For the mass term this leaves only the possibility to write[12]

$$C^{b_1 \dots b_9 | a_1 \dots a_8} = e^{-5\phi/4} P^{b_1 \dots b_9} P^{a_1 \dots a_8} \,. \tag{5.6}$$

This is indeed the correct corresponding constraint if set to zero. Furthermore, this expression is weakly conserved along the geodesic motion, as immediately follows from the coset model equations of motion in Appendix C.1.

After using the dictionary of Table 2, the coset constraint (5.6) turns into the expression

$$\begin{aligned} C^{b_1 \dots b_9 | a_1 \dots a_8} &= -\frac{1}{4} N^2 m \, e^{5\phi/4} \epsilon^{b_1 \dots b_9} \epsilon^{a_1 \dots a_8 c} \partial_c \phi \\ &= -\frac{N}{4} \epsilon^{b_1 \dots b_9} \epsilon^{a_1 \dots a_8 c} \partial_c \left(e^{5\phi/4} m \right) \end{aligned} \tag{5.7}$$

which indeed vanishes in supergravity as a consequence of the truncation (A.12b). Therefore we find an extension of the set of constraints of [16] to include the mass generator. It would be interesting to investigate in detail to what extent the Sugawara-type structure found there continues to apply on this next level.

Besides the bosonic constraints one also has to ensure that the supersymmetry $\mathcal{S}$ constraint arising from fixing (4.10) to zero is satisfied. This constraint was already studied in detail in [21, 16] where it was shown that it also gives rise to the bosonic constraints, in particular the Hamiltonian constraint, in a canonical analysis. This is in agreement with the general result of [58] that the supersymmetry constraint is the 'square-root' of the bosonic constraints.

---

[12] Here, we have written out the trailing ϵ (in the form of an extra set $[b_1 \dots b_9]$ of antisymmetric indices on the constraint) and the correct dilaton pre-factor for this level.

5.3 The gauge algebra

We now consider the gauge algebra of massive IIA supergravity in $D = 10$ and its relation to global Kac–Moody transformations. It is instructive to start the discussion in a covariant setting where the associated Kac–Moody transformations should belong to E_{11} [23]. We then show how the gauge-fixing in the case of E_{10} reconciles the local nature of gauge transformations with the global nature of E_{10} rotations both in the undeformed and in the deformed case.

From the definition of the field strengths (2.2) it follows that the tensor gauge transformations of the massive supergravity gauge potentials are (see also [47, 28])

$$\begin{aligned} \delta_\Lambda A_\mu &= \partial_\mu \Lambda - m\Lambda_\mu \,, \\ \delta_\Lambda A_{\mu_1\mu_2} &= 2\partial_{[\mu_1}\Lambda_{\mu_2]} \,, \\ \delta_\Lambda A_{\mu_1\mu_2\mu_3} &= 3\partial_{[\mu_1}\Lambda_{\mu_2\mu_3]} + 3A_{[\mu_1\mu_2}\delta_\Lambda A_{\mu_3]} \,. \end{aligned} \tag{5.8}$$

Each p-form has its own $(p-1)$-form gauge parameter and the field strengths in (2.2) are invariant under these gauge transformations.

In the massless case, the algebra of gauge transformations displays a hierarchical or Borel-type structure in that every form only transforms under its own gauge parameter or under gauge transformations of the lower rank p-forms. These couplings are determined by Chern–Simons terms or the so-called transgression terms (like $4A_{[\mu_1}F_{\mu_2\mu_3\mu_4]}$ in (2.2)). This pattern persists also when higher rank p-forms are introduced in the supersymmetry algebra [59] and is reminiscent of a Borel type structure on the positive step operators of E_{11} (or also E_{10}) [23, 28]. In the massive case, however, the hierarchy appears to be broken as now the vector field A_μ transforms under the gauge parameter Λ_μ of the two-form, leading to the Stückelberg mechanism.

In order to make the correspondence between E_{10} or E_{11} and the algebra of gauge transformations more precise we rewrite (5.8) for any value of m as

$$\begin{aligned} \delta_\Sigma A_\mu &= \Sigma_\mu \,, \\ \delta_\Sigma A_{\mu_1\mu_2} &= \Sigma_{\mu_1\mu_2} \,, \\ \delta_\Sigma A_{\mu_1\mu_2\mu_3} &= \Sigma_{\mu_1\mu_2\mu_3} + 3\Sigma_{[\mu_1}A_{\mu_2\mu_3]} \,, \end{aligned} \tag{5.9}$$

by absorbing the derivatives and the mass term into the definition of the Σ.[13] It is straightforward to show that for example

$$\left[\delta_{\Sigma_{\mu_1\mu_2}}, \delta_{\Sigma_{\mu_3}}\right] = \delta_{\Sigma_{\mu_1\mu_2\mu_3}} \tag{5.10}$$

on all fields, where the parameter $\Sigma_{\mu_1\mu_2\mu_3}$ is expressed through the constituent Λ parameters.

---

[13] Note that for $m \neq 0$, Σ_μ is no longer closed.

The commutator (5.10) resembles the commutator (3.11) between the level $(1,0)$ and $(0,1)$ generators. This is not purely coincidental as can be seen from considering the action of a global E_{10} transformation of the coset element (5.1) by a Borel element, i.e. $g \in E_{10}^{+}$ such that g is an exponential of positive step operators only. Evaluating the action $\mathcal{V} \mapsto \mathcal{V}g$ requires no compensating $K(E_{10})$ transformation in this case since Borel-valued g preserve the Borel gauge. For example, for

$$g = e^{\Sigma_m E^m} e^{\frac{1}{2}\Sigma_{m_1 m_2} E^{m_1 m_2}} e^{\frac{1}{3!}\Sigma_{m_1 m_2 m_3} E^{m_1 m_2 m_3}} \tag{5.11}$$

one can compute the resulting transformation of the coset fields to lowest order in the Σ parameters to be

$$\begin{aligned} A_m &\longmapsto A_m + \Sigma_m \,, \\ A_{m_1 m_2} &\longmapsto A_{m_1 m_2} + \Sigma_{m_1 m_2} \,, \\ A_{m_1 m_2 m_3} &\longmapsto A_{m_1 m_2 m_3} + \Sigma_{m_1 m_2 m_3} + 3\Sigma_{[m_1} A_{m_2 m_3]} \,. \end{aligned} \tag{5.12}$$

This is in exact agreement with the gauge transformations (5.9) for the spatial components of the gauge fields. A similar reasoning can be carried out for E_{11} [23] and the formulæ are the same but with covariant space-time indices.

However, this appears to pose a problem since the gauge transformations (5.9) are local transformations and the E_{10} (or E_{11}) transformations (5.12) are global. In [28] the resolution of this problem was suggested to be to take the global limit of the Σ parameters in supergravity.[14] For undeformed supergravity, this is tantamount to considering gauge parameters Λ in (5.8) which are linearly space-time dependent. As was already pointed out in [28], for the mass deformed model the appearance of a naked Λ_μ in the variation of the vector field makes this limit inconsistent since then

$$\Sigma_\mu = \partial_\mu \Lambda - m\Lambda_\mu \tag{5.13}$$

is no longer constant. In the covariant E_{11} formulation, one possibility to resolve this inconsistency considered in [28] is to introduce so-called (-1)-forms (see also [47, 35]) which enlarge the gauge algebra. The enlarged gauge algebra should be compared with the combined algebra of E_{11} and the momentum representation l_1 of E_{11} [57, 24, 26]. The result of [28] was that these two algebras are different: the additional fields required for closing the algebra once a (-1)-form is present are not those of the l_1 representation. Consequently the problem was not resolved in the covariant framework.

---

[14] This is the general way the global part of the higher-dimensional diffeomorphisms and gauge transformations gets inherited by the parabolic subgroup of the hidden symmetry group after dimensional reduction. It would be interesting to study the usual hidden symmetries of the massive theory, something that has not been done to the best of our knowledge.

Here, we work in a gauge-fixed E_{10} framework and therefore the question has to be investigated anew. In the E_{10} context, the global nature of a transformation refers to its time-dependence. As all comparisons are assumed to be carried out at a fixed spatial point all space-dependence is 'frozen'. Furthermore, only gauge-fixed quantities are compared. To preserve the temporal gauge (4.3) of supergravity one has to include compensating gauge transformations. We will denote these compensated gauge transformations by $\hat{\delta}_\Lambda$, for example

$$\hat{\delta}_\Lambda A_\mu = \delta_\Lambda A_\mu + S_\mu \tag{5.14}$$

and S_μ denotes the compensator whose precise form we will not require. The compensators are fixed by demanding that the temporal gauge is preserved, i.e.

$$\hat{\delta}_\Lambda A_t = 0\,, \quad \hat{\delta}_\Lambda A_{tm} = 0\,, \quad \hat{\delta}_\Lambda A_{tm_1m_2} = 0\,. \tag{5.15}$$

Since field strengths are gauge invariant, we obtain immediately

$$0 = \hat{\delta}_\Lambda F_{tm} = \partial_t \hat{\delta}_\Lambda A_m - \partial_m \hat{\delta}_\Lambda A_t + m \hat{\delta}_\Lambda A_{tm} = \partial_t \hat{\delta}_\Lambda A_m\,, \tag{5.16}$$

so that $\hat{\delta}_\Lambda A_m$ is time-independent and hence can be associated with a global E_{10} transformation. In this way, the gauge-fixing resolves the tension between the global nature of E_{10} transformations and local gauge transformations in supergravity. The local $K(E_{10})$ transformations have been fixed by adopting the (almost) Borel gauge so that there are no local gauge transformations left in the σ-model (except for the level $\ell = (0,0)$ Lorentz rotations), in agreement with the time-independence of the gauge transformation in gauge-fixed supergravity. This argument is valid both for the massless and the massive case.

5.4 Supersymmetry variation of the bosons from E_{10}

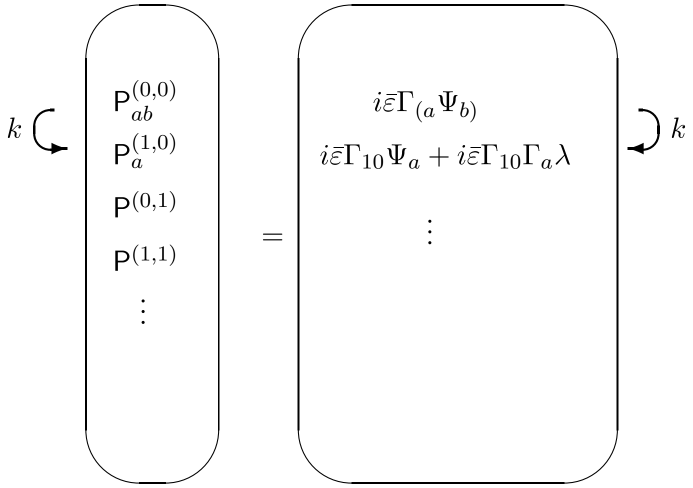
We define a supersymmetry variation of the coset element $\mathcal{V}$ via

$$\delta_\epsilon \mathcal{V}\mathcal{V}^{-1} = \mathsf{P} + \mathsf{Q} \quad \in \mathfrak{e}_{10}\,. \tag{5.17}$$

From the explicit form of (5.1) we obtain for the first few levels

$$\begin{aligned}
\mathsf{P} \;=\; & -\frac{1}{2} e_a{}^m \delta_\epsilon e_{mb} S^{ab} + \delta_\epsilon \phi T + \frac{1}{2} e^{3\phi/4} e_a{}^m \delta_\epsilon A_m (E^a + F_a) \\
& + \frac{1}{4} e^{-\phi/2} e_{a_1}{}^{m_1} e_{a_2}{}^{m_2} \delta_\epsilon A_{m_1m_2} (E^{a_1a_2} + F_{a_1a_2}) \\
& + \frac{1}{12} e^{\phi/4} e_{a_1}{}^{m_1} e_{a_2}{}^{m_2} e_{a_3}{}^{m_3} \delta_\epsilon A_{m_1m_2m_3} (E^{a_1a_2a_3} + F_{a_1a_2a_3}) + \ldots\,.
\end{aligned} \tag{5.18}$$

The supersymmetry variations of the bosonic fields can now be computed from the following observation [21]. The Lie algebra element P transforms under $K(E_{10})$ in the coset



k
$\mathsf{P}^{(0,0)}_{ab}$
$\mathsf{P}^{(1,0)}_{a}$
$\mathsf{P}^{(0,1)}$
$\mathsf{P}^{(1,1)}$
$\vdots$
$=$
$i\bar{\varepsilon}\Gamma_{(a}\Psi_{b)}$
$i\bar{\varepsilon}\Gamma_{10}\Psi_a + i\bar{\varepsilon}\Gamma_{10}\Gamma_a\lambda$
$\vdots$
k

Figure 4: *Illustration of the two ways of transforming the coset representation* $\mathsf{P} = \epsilon \odot \Psi$ *with an element* $k \in K(E_{10})$*: Either using the abstract coset representation* P *or the explicit expression in terms of* $K(E_{10})$ *fermion bilinears. The fermion bilinear expressions are only meant to be indicative for space reasons. The exact expressions are given in the text.*

representation. So one can obtain any higher level component from a $K(E_{10})$ rotation of level zero.[15] At the same time one can take the explicit expressions for the supersymmetry variations of the level zero fields from supergravity in terms of fermions and interpret the resulting expression as being constructed out of the tensor product of the **32** Dirac-spinor representation and the **320** vector-spinor representation of $K(E_{10})$. Then one can compute the $K(E_{10})$ action on an expression of the type $\mathsf{P} = \epsilon \odot \Psi$ in two different ways; either by transforming P according to the coset transformation, or by transforming the fermion bilinear according to the unfaithful spinor representations, see Figure 4. Equating the two results yields an expression for the supersymmetry variation of the higher level (bosonic) coset fields. This procedure rests on the assumption that the expression bilinear in the fermions transforms in exactly the same way as the coset variable. This is known to be incorrect at higher levels [21] (notably from the level of the dual graviton onwards) and is related to the fact that there is a certain disparity between the fermionic fields in unfaithful finite-dimensional representations of $K(E_{10})$ whereas the bosons transform in the infinite-dimensional coset representation. This point certainly requires further investigation.

---

[15] In fact, one can obtain any element from the Cartan subalgebra. The converse is not true: One cannot conjugate an arbitrary element of the coset into the Cartan subalgebra, unlike in the finite-dimensional case. This derives from the general property of infinite-dimensional Kac-Moody algebras that any element of the algebra is no longer conjugate to a Cartan element [60].

Irrespective of the known obstacles at higher levels, we illustrate this procedure now for the lowest lying bosonic fields. Under a $K(E_{10})$ rotation with generator

$$\delta k = \Lambda_a (E^a - F_a) \tag{5.19}$$

the coset element P transforms infinitesimally as $\delta_{\delta k}\mathsf{P} = [\delta k, \mathsf{P}]$ leading to

$$\begin{aligned}\delta_{\delta k}\mathsf{P} &= e_{(a}{}^m \delta_\epsilon e_{mb)} \Lambda_b (E^a + F_a) - \frac{3}{4}\delta_\epsilon \phi \Lambda_a (E^a + F_a) + \frac{3}{2} e^{3\phi/4} e_c{}^m \delta_\epsilon A_m \Lambda_c T \\ &\quad - \frac{1}{16} e^{3\phi/4} e_c{}^m \delta_\epsilon A_m \Lambda_c \delta_{ab} S^{ab} + \frac{1}{2} e^{3\phi/4} e_a{}^m \delta_\epsilon A_m \Lambda_b S^{ab} + \ldots \,.\end{aligned} \tag{5.20}$$

This is the first way of transforming $\mathsf{P} = \epsilon \odot \Psi$. Transforming instead the fermion bilinear of level zero, using the formulæ (3.23), (3.25) and (3.26) leads for the coefficient of the dilaton generator T to

$$\delta_{\delta k}(i\bar{\varepsilon}\lambda) = i\Lambda_a \left(\frac{9}{8} \bar{\varepsilon} \Gamma^a \Gamma_{10} \lambda + \frac{3}{2} \bar{\varepsilon} \Gamma_{10} \psi_a \right) , \tag{5.21}$$

where also the dictionary of Table 2 was used. Comparing the two expressions we deduce

$$\delta_\epsilon A_m = i e^{-3\phi/4} \left(\bar{\varepsilon} \Gamma_{10} \psi_m + \frac{3}{4} \bar{\varepsilon} \Gamma_m \Gamma_{10} \lambda \right) \tag{5.22}$$

in complete agreement with (2.7). This procedure can be pushed to higher level and yields the supersymmetry variations of all bosonic fields from the variation of the dilaton. From the level of the dual graviton onwards there appear the known problems [21] related to the non-supersymmetry of the bosonic-fermionic coset model of section 3.4. Nevertheless this kind of calculation is a useful tool for studying and deriving supersymmetry transformation rules from Kac–Moody algebra. We also note that the same reasoning works in exactly the same way for E_{11} since the Maurer–Cartan form (5.20) involves a supersymmetry variation and therefore no closure with the conformal group is required.[16] We also checked that the same analysis in the case of $D = 11$ supergravity reproduces correctly the transformations of the three-form and the six-form including all contributions from the Chern–Simons term and transgression terms.

---

[16] This closure plays an important role in constructing field strengths out of $\partial_\mu \mathcal{V}\mathcal{V}^{-1}$ for E_{11} since the μ index needs to be antisymmetrized with the indices on the generators [23]. The conformal group enters in this discussion due to a theorem by Ogievetsky [61] giving an algebraic description of the algebra of diffeomorphisms as the closure of affine diffeomorphisms with conformal diffeomorphisms. The notion of conformal group is in fact misleading here as there is no conformal invariance in the theory. All that is required for the theorem is to have a suitable diffeomorphism generator which is quadratic in the coordinates. After commutation it will yield diffeomorphism generators with arbitrary polynomial dependence on the coordinates.

6 Trombone deformations and the dual graviton

In a recent interesting paper [42] it was remarked that it is possible to systematically construct also deformed supergravity theories by using an appropriate embedding tensor if one gauges a global scaling symmetry of the equations of motion. Under this scaling or *trombone symmetry*, all bosonic tensor fields scale with a weight proportional to the number of their tensor indices:

$$G_{\mu\nu} \mapsto \Lambda^2 G_{\mu\nu}\,, \quad A_{\mu_1\dots\mu_p} \mapsto \Lambda^p A_{\mu_1\dots\mu_p}\,. \tag{6.1}$$

The fermions also scale appropriately such that the whole massless action scales as[17]

$$\mathcal{L}^{[B]} + \mathcal{L}^{[F]} \mapsto \Lambda^{D-2}\left(\mathcal{L}^{[B]} + \mathcal{L}^{[F]}\right) \tag{6.2}$$

in D space-time dimensions. This is only a symmetry of the action in $D = 2$ space-time dimensions. Otherwise it is nevertheless an acceptable global symmetry of the equations of motion. In the framework of gauging subgroups of global symmetry groups one can also consider gauging this trombone symmetry and obtain a deformed supergravity theory if one is willing to give up the existence of an action from which the deformed equations of motion are derived. This was already done in the $D = 10$ type IIA case in [40, 41]. The analysis of [42] sheds new light on this somewhat neglected class of deformed supergravities and the relation to Kac–Moody symmetries by the following observation. In a given space-time dimension $D \geq 3$, undeformed maximal supergravity has a global symmetry group E_{11-D} under which the vector fields transform in a certain representation. The embedding tensor describing the gauging of the trombone symmetry therefore has to transform in the representation dual to the vector fields in order to construct the covariant derivative. By inspection of the decomposition tables of [25] one finds that exactly this representation occurs in the level decomposition of E_{10} or E_{11} on the same level as the representations relevant for the 'usual' embedding tensor which describes gaugings of the global E_{11-D} symmetry rather than of the trombone.

The crucial difference is, however, that while from a space-time point of view the usual embedding tensor is related to $(D-1)$-forms, the trombone embedding tensor occurs in the tables of E_{10} and E_{11} as a *mixed symmetry tensor* according to the observation of [42]. The mixed symmetry is a hook symmetry of type $(D-2, 1)$ with also a total of $(D-1)$ boxes. While it is clear how to associate to a $(D-1)$-form a single constant deformation parameter g (the gauge coupling) by passing to a constant space-time filling field strength (just like for the Romans mass), this is not so obvious for the $(D-2, 1)$ mixed symmetry tensor conjectured to be of relevance for the trombone deformation. One first observation is that a mixed $(D-2,1)$ tensor in D dimensions carries no degrees of freedom [62, 63, 42].

---

[17] We note that for this to be true in Romans theory, the mass has to be replaced by a nine-form which scales according to the general rule.

Here, we would like to point out that in $D=10$ this $(8,1)$ hook tensor arises at level $(3,3)$ as can be seen from the extended level decomposition in Table 5 in Appendix B.1. This implies that it is part of the $D=11$ dual graviton (which is the only representation at $\ell_1=3$ under $\mathfrak{sl}(10,\mathbb{R})$ [8]) and inspection of the associated root vector confirms that its lowest weight vector belongs to E_9. This is again in contrast with the other deformations which were all genuine E_{10} generators not visible in $D=11$ supergravity. The same is true when one continues to lower dimensions where always the lowest weight vector is part of E_9. Acting with $GL(D-1,\mathbb{R})$ will of course also lead to root vectors which are genuine E_{10} elements.

6.1 Comparing the reduction of p-forms and their duals

The fact that the hook arises from the $D=11$ dual graviton by dimensional reduction is indicative of a general phenomenon. For forms of 'extreme rank' there is a difference in reducing the field or its dual. Before discussing this for the trombone generator and the dual graviton, let us study this for p-forms.

In the antisymmetric p-form case 'extreme rank' means $p=0$: The reduction of an axionic scalar[18] from D to $D-1$ dimensions gives a scalar and nothing else. The dual of a scalar in D dimensions is a $(D-2)$-form which reduces to a $(D-3)$-form, which is dual to a scalar in $D-1$ dimensions, and a $(D-2)$-form which carries no propagating degrees of freedom in $D-1$ dimensions. From the point of view of counting degrees of freedom this is satisfactory but it turns out that the $(D-2)$-form can have an effect on the reduced theory. To see this consider the reduction of gravity in D dimensions coupled to a $(D-2)$-form

$$S^{(D)} = \int d^D x \sqrt{-\hat{G}} \left(\hat{R} - \frac{1}{2(D-1)!} \hat{F}^2_{(D-1)} \right) , \tag{6.3}$$

where we denote with hats the quantities in D dimensions. This is classically equivalent to a scalar field χ coupled to gravity (for scalar fields hats are superfluous)

$$S^{(D)} = \int d^D x \sqrt{-\hat{G}} \left(\hat{R} - \frac{1}{2} (\partial\chi)^2 \right) , \tag{6.4}$$

where the two fields are dual via

$$\hat{F}_{\mu_1 \dots \mu_{D-1}} = \epsilon_{\mu_1 \dots \mu_{D-1} \nu} \partial^\nu \chi \, . \tag{6.5}$$

---

[18] 'Axionic' here refers to the fact that the scalar enters the Lagrangian only with derivatives and so has a global shift symmetry, see (6.4).

Returning to the action (6.3) in terms of the $(D-2)$-form and reducing one finds with the standard rules

$$\begin{aligned} S^{(D-1)} &= \int d^{D-1}x\sqrt{-G}\Big(R - \frac{1}{2}(\partial\phi)^2 - \frac{1}{4}e^{\gamma\phi}F_{(2)}^2 \\ &\qquad -\frac{1}{2(D-1)!}e^{\gamma\phi}F_{(D-1)}^2 - \frac{1}{2(D-2)!}F_{(D-2)}^2\Big)\,. \end{aligned} \qquad (6.6)$$

The first line contains the usual reduced metric, the dilaton ϕ and the graviphoton field strength. Here, $\gamma = \pm\sqrt{2(D-2)/(D-3)}$, in agreement with the exponent in (2.1). The definitions of the reduced field strength $F_{(D-1)}$ involves a coupling to the graviphoton via a transgression term whose precise form will not be relevant as it does not influence the Bianchi identity for $F_{(D-1)}$ which states that $F_{(D-1)}$ is a constant, which we call M, times the ϵ tensor. Therefore, there will be an effective (positive) cosmological term proportional to $e^{\gamma\phi}M^2$, which also acts as a potential for the dilaton obtained from reduction. Furthermore, it creates a linear interaction term of the type $M * F_{(D-2)}$ in the equation of motion of the graviphoton $F_{(2)}$ (due to the transgression term) and also a linear interaction term proportional to $M * F_{(2)}$ in the equation of motion of $F_{(D-2)}$.

These features are to be contrasted with what one would obtain from the straight reduction of the scalar model (6.4). There no such effect arises: The scalar field is still free and there is no cosmological constant. Hence, *reducing a scalar* 0*-form or its dual* $(D-2)$*-form gives different results.* This can be understood also from the duality relation (6.5). Having a constant $F_{(D-1)}$ field strength means that χ has to be *linear* in the extra direction with slope M.[19] This shows that the reduction of a scalar field in terms of its dual field is only an honest dimensional reduction if $M=0$. For $M \neq 0$ one obtains a more general reduction; in fact a Scherk–Schwarz reduction [64, 41].

6.2 The trombone and the dual graviton

After this digression let us return to the dual graviton and the trombone deformations. It is known that linearized gravity in D dimensions can be rewritten in terms of a dual graviton $\tilde{h}_{\rho|\mu_1\dots\mu_{D-3}}$ which transforms irreducibly in a $(D-3,1)$ hook representation of $GL(D,\mathbb{R})$ and carries the same number of degrees of freedom as the graviton $h_{\mu\nu}$ [9, 65–67, 63].[20] Now consider the dimensional reduction of the graviton and the dual graviton which is summarized for the reduction from five to four dimensions in Figure 5. As is evident from the diagram, and also generally, the reduction will not produce dual fields in a balanced way. The graviton in D dimensions gives a scalar, a Maxwell field and the graviton in

---

[19] We ignore the transgression term in this discussion.

[20] The construction of an interacting theory solely in terms of the dual graviton is impossible under rather general assumptions [68]. For a non-linear model containing both the graviton and its dual as well as an auxiliary field see [69, 70].

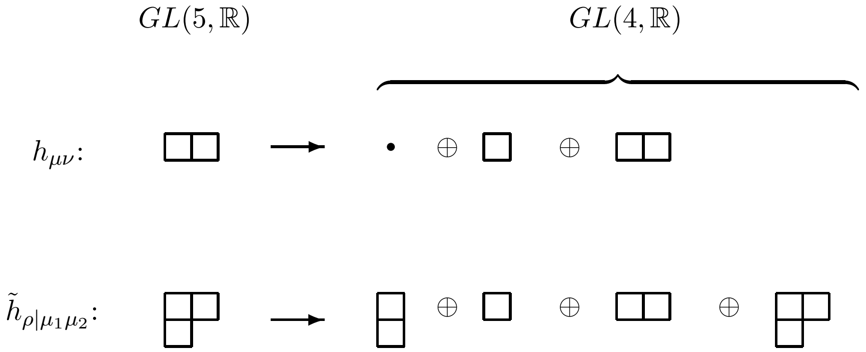


Figure 5: *Dimensional reduction of graviton $h_{\mu\nu}$ and dual graviton $\tilde{h}_{\rho|\mu_1\ldots\mu_{D-3}}$ from D dimensions to $D-1$ dimensions in terms of irreducible representations of $GL(D,\mathbb{R})$ and $GL(D-1,\mathbb{R})$ for $D=5$. Objects in the same column are related by duality (in the linearised theory).*

$D-1$ dimensions. The dual graviton in D dimensions gives a dual scalar, a dual vector, a dual graviton in $D-1$ dimensions and one more field of mixed symmetry type. This extra field has hook symmetry of type $(D-3,1)$ in $(D-1)$ dimensions and arises from the dual graviton in higher dimensions when none of the indices lies in the extra direction. For the reduction from $D=11$ to $D=10$ this is exactly the $(8,1)$ form that arises on level $(3,3)$ in the decomposition of E_{10}.[21]

The extra field carries no degrees of freedom but it could change the dynamics if it is non-zero, in analogy with the scalar example above. The reason why the dual scalar field in the p-form example influenced the reduced dynamics was that one could associate in a gauge invariant manner a constant to its field strength. In other words, the top de Rham cohomology is non-empty, and one-dimensional. Repeating the same kind of analysis for the mixed symmetry type tensor arising from the reduction of the dual graviton one finds instead that there is no gauge invariant quantity one could associate with because the corresponding cohomology is empty [65,67,63]. For this reason we are led to the conclusion that the immediate association of the trombone gauging with the $(D-2,1)$-forms appearing in the E_{10} or E_{11} tables is problematic. One possible resolution of this puzzle could be to add a new generator to the algebra which transforms as a 9-form in eleven dimensions. This new generator would appear for the first time at height 30 and change the multiplicity of the null root of E_{10} (or E_{11}) from eight to nine.In the eleven-dimensional language it would, after using the dictionary [8,15], correspond to the trace of the spin connection which is always set to zero when establishing the correspondence. Naturally, this term would contribute to the $(D-1)$-forms in D dimensions and would transform in the same E_{11-D} representation as the $(D-2,1)$ hook which was conjectured for the trombone gauging. In this way one would also find the right object to treat trombone gauging in the level decomposition. It is not clear, however, that this is the right path to pursue since it is known that adding this generator creates problems in the E_{10} sigma model [16]. One possible habitat for such a new generator outside the E_{10} algebra would be the vertex operator algebra based on the E_{11} root lattice. This possibility is investigated in some more depth in Appendix D where it is argued that also the trombone gaugings would not be recovered correctly from this modification of the algebra.

---

[21] Going down in dimensions one finds parts of the E_{11-D} multiplets of the conjectured trombone deformation tensors to arise in this way while others come also from different sources.

Irrespective of these speculations about new generators, one can analyse the effect of the hook on level $(3,3)$ on the geodesic equations. This is carried out in Appendix D and we verify that for $D=10$ the interpretation of the mixed symmetry field as being associated to the trombone is correct forasmuch as it modifies the equations of motion of the IIA supergravity fields in almost the same way as is to be expected from the deformed theory of [40, 41]. The final resolution of this question could shed new light on the role of mixed symmetry fields appearing in the level decomposition of E_{10} (and E_{11}).

Acknowledgements

We are grateful to Xavier Bekaert, Eric A. Bergshoeff, Jarah Evslin, Ulf Gran, Laurent Houart, Olaf Hohm, Bernard Julia, Carlo Maccaferri, Hermann Nicolai, Teake Nutma, Jakob Palmkvist, Christoffer Petersson, Henning Samtleben and Alexander Wijns for interesting discussions. We would also like to thank Ulf Gran for extensive aid in the use of the computer program GAMMA. M.H. and D.P. are grateful to the 'Laboratoire de Physique Théorique de l'Ecole Normale Supérieure' for kind hospitality while this work was being finalized. A Details for massive IIA supergravity

In this appendix we give all the relevant details of massive IIA supergravity which are required to establish the correspondence with the E_{10}-sigma model. The complete Lagrangian and supersymmetry variations were already given in Section 2, and will not be repeated here. Here we complement this with information regarding our conventions, as well as explicit expressions for the bosonic and fermionic equations of motion, and the Bianchi identities. Moreover, we discuss in detail the truncations that we need to impose on the supergravity side to ensure the matching with the geodesic sigma model. Finally, we also discuss how our conventions for massless type IIA supergravity matches with a reduction from eleven-dimensional supergravity.

A.1 Conventions

We use the signature $(- + \ldots +)$ for space-time. The indices $\mu = (t, m)$ are $(1+9)$-dimensional curved indices, whereas $\alpha = (0, a)$ are the corresponding flat indices. Partial derivatives with flat indices are defined via conversion with the inverse vielbein: $\partial_\alpha = e_\alpha{}^\mu \partial_\mu$. The Lorentz covariant derivative D_α acts on (co-)vectors via $D_\alpha V_\beta = \partial_\alpha V_\beta + \omega_{\alpha\,\beta}{}^\gamma V_\gamma$ in terms of the Lorentz connection, which is defined in turn as

$$\omega_{\alpha\,\beta\gamma} = \frac{1}{2}\left(\Omega_{\alpha\beta\,\gamma} + \Omega_{\gamma\alpha\,\beta} - \Omega_{\beta\gamma\,\alpha}\right) \tag{A.1}$$

in terms of the anholonomy of the orthonormal frame $e_\mu{}^\alpha$ defined by $\Omega_{\mu\nu}{}^\alpha = 2\partial_{[\mu} e_{\nu]}{}^\alpha$.

Our fermions are Majorana–Weyl spinors of $SO(1,9)$ of real dimension 16. As the theory is type II non-chiral we can combine two spinors into a 32-dimensional Majorana representation on which the Γ-matrices of $SO(1,10)$ act. These are the eleven real 32×32 matrices $(\Gamma^0, \Gamma^a, \Gamma^{10})$ which are symmetric except for Γ^0 which is antisymmetric. We choose the representation such that Γ^{10} is block diagonal and projects on the two 16 component spinors of opposite chirality. Γ^0 is the charge conjugation matrix such that our conventions are identical to those of [36].

A useful identity for our Γ-matrices is

$$\Gamma^{a_1 \ldots a_k} = \frac{(-1)^{(k+1)(k+2)/2}}{(9-k)!} \epsilon^{a_1 \ldots a_k b_1 \ldots b_{9-k}} \Gamma_{b_1 \ldots b_{9-k}} \Gamma^0 \Gamma^{10}\,. \tag{A.2}$$

The various ϵ tensors we use are such that

$$\epsilon^{0\,1 \ldots 10} = +1\,, \quad \epsilon^{0\,1 \ldots 9} = +1\,, \quad \epsilon^{1\,\ldots 9} = +1\,. \tag{A.3}$$

A.2 Bianchi identities

For the comparison with E_{10} it is useful to write all supergravity equations in a non-coordinate orthonormal frame described by the vielbein $e_\mu{}^\alpha$ and use only Lorentz covariant objects. In these flat indices the Bianchi identities following from (2.2) are

$$3D_{[\alpha_1}F_{\alpha_2\alpha_3]} = mF_{\alpha_1\alpha_2\alpha_3}\,, \tag{A.4a}$$

$$4D_{[\alpha_1}F_{\alpha_2\alpha_3\alpha_4]} = 0\,, \tag{A.4b}$$

$$5D_{[\alpha_1}F_{\alpha_2\alpha_3\alpha_4\alpha_5]} = 10F_{[\alpha_1\alpha_2}F_{\alpha_3\alpha_4\alpha_5]}\,. \tag{A.4c}$$

A.3 Bosonic equations of motion

The form equations of motion can be rewritten in 10-dimensional flat indices as

$$D_\alpha(e^{3\phi/2}F^{\alpha\beta}) = -\frac{1}{3!}e^{\phi/2}F^{\alpha_1\alpha_2\alpha_3\beta}F_{\alpha_1\alpha_2\alpha_3}\,, \tag{A.5a}$$

$$\begin{aligned} D_\alpha(e^{-\phi}F^{\alpha\beta_1\beta_2}) &= me^{3\phi/2}F^{\beta_1\beta_2} + \frac{1}{2!}e^{\phi/2}F^{\beta_1\beta_2\alpha_1\alpha_2}F_{\alpha_1\alpha_2} \\ &\quad -\frac{1}{1152}F_{\alpha_1\ldots\alpha_4}F_{\alpha_5\ldots\alpha_8}\epsilon^{\alpha_1\ldots\alpha_8\beta_1\beta_2}\,, \end{aligned} \tag{A.5b}$$

$$D_\alpha(e^{\phi/2}F^{\alpha\beta_1\ldots\beta_3}) = \frac{1}{144}F_{\alpha_1\ldots\alpha_4}F_{\alpha_5\ldots\alpha_7}\epsilon^{\alpha_1\ldots\alpha_7\beta_1\ldots\beta_3}, \tag{A.5c}$$

while the dilaton and gravity equations are

$$D^\alpha\partial_\alpha\phi = \frac{3}{8}e^{3\phi/2}|F_{(2)}|^2 - \frac{1}{12}e^{-\phi}|F_{(3)}|^2 + \frac{1}{96}e^{\phi/2}|F_{(4)}|^2 + \frac{5}{4}m^2e^{5\phi/2}\,, \tag{A.6a}$$

$$\begin{aligned} R_{\alpha\beta} &= \frac{1}{2}\partial_\alpha\phi\partial_\beta\phi + \frac{m^2}{16}\eta_{\alpha\beta}e^{5\phi/2} + \frac{1}{2}e^{3\phi/2}F_{\alpha\gamma}F_\beta{}^\gamma - \frac{1}{32}\eta_{\alpha\beta}e^{3\phi/2}F_{\gamma_1\gamma_2}F^{\gamma_1\gamma_2} \\ &\quad +\frac{1}{4}e^{-\phi}F_{\alpha\gamma_1\gamma_2}F_\beta{}^{\gamma_1\gamma_2} - \frac{1}{48}\eta_{\alpha\beta}e^{-\phi}F_{\gamma_1\gamma_2\gamma_3}F^{\gamma_1\gamma_2\gamma_3} \\ &\quad +\frac{1}{12}e^{\phi/2}F_{\alpha\gamma_1\gamma_2\gamma_3}F_\beta{}^{\gamma_1\gamma_2\gamma_3} - \frac{1}{128}\eta_{\alpha\beta}e^{\phi/2}F_{\gamma_1\gamma_2\gamma_3\gamma_4}F^{\gamma_1\gamma_2\gamma_3\gamma_4}. \end{aligned} \tag{A.6b}$$

A.4 Fermionic equations of motion

Besides the bosonic equations one also deduces the fermionic equations of motion from the Lagrangian (2.1) which we write out in flat indices. For the dilatino this gives

$$\begin{aligned} \Gamma^\alpha D_\alpha\lambda &- \frac{5}{32}e^{3\phi/4}F_{\alpha_1\alpha_2}\Gamma^{\alpha_1\alpha_2}\Gamma_{10}\lambda + \frac{3}{16}e^{3\phi/4}F_{\alpha_1\alpha_2}\Gamma^\beta\Gamma^{\alpha_1\alpha_2}\Gamma_{10}\psi_\beta \\ &+ \frac{1}{24}e^{-\phi/2}F_{\alpha_1\cdots\alpha_3}\Gamma^\beta\Gamma^{\alpha_1\cdots\alpha_3}\Gamma_{10}\psi_\beta \\ &+ \frac{1}{128}e^{\phi/4}F_{\alpha_1\cdots\alpha_4}\Gamma^{\alpha_1\cdots\alpha_4}\lambda - \frac{1}{192}e^{\phi/4}F_{\alpha_1\cdots\alpha_4}\Gamma^\beta\Gamma^{\alpha_1\cdots\alpha_4}\psi_\beta \\ &- \frac{1}{2}\partial_\alpha\phi\Gamma^\beta\Gamma^\alpha\psi_\beta \\ &- \frac{21}{16}me^{5\phi/4}\lambda - \frac{5}{8}me^{5\phi/4}\Gamma^\alpha\psi_\alpha = 0, \end{aligned} \tag{A.7}$$

The gravitino equation obtained directly from the variation of (2.1) is of the form

$$\mathcal{E}^\alpha = \Gamma^{\alpha\beta\gamma}D_\beta\psi_\gamma + R^\alpha = 0. \tag{A.8}$$

After multiplication with two gamma matrices it can be rewritten as

$$E_\alpha = \Gamma^\beta (D_\alpha \psi_\beta - D_\beta \psi_\alpha) + L_\alpha = 0, \tag{A.9}$$

where

$$L_\alpha = \frac{1}{8}(\Gamma_{\alpha\beta} R^\beta - 7R_\alpha), \tag{A.10}$$

Although $\mathcal{E}^\alpha = 0$ is equivalent to $E^\alpha = 0$, the spatial components E^a and $\mathcal{E}^a$ are only equivalent when the supersymmetry constraint $\mathcal{E}^0$ is also taken into account. It turns out that the dynamical equation that corresponds directly to the $K(E_{10})$ Dirac equation is $E^a = 0$, not too surprisingly since in this form one obtains directly a Dirac equation for ψ_a. The $SO(1,9)$ covariant equation $E_\alpha = 0$ reads explicitly as follows:

$$\begin{aligned}
\Gamma^\beta\left(D_\alpha\psi_\beta - D_\beta\psi_\alpha\right) \quad &+ \quad \frac{21}{64}e^{3\phi/4}F_{\alpha\beta}\Gamma^\beta\Gamma_{10}\lambda - \frac{3}{128}e^{3\phi/4}F_{\beta_1\beta_2}\Gamma_\alpha{}^{\beta_1\beta_2}\Gamma_{10}\lambda \\
&+ \quad \frac{1}{64}e^{3\phi/4}F_{\beta_1\beta_2}\Gamma_\alpha{}^{\beta_1\beta_2\gamma}\Gamma_{10}\psi^\gamma - \frac{1}{32}e^{3\phi/4}F_{\beta_1\beta_2}\Gamma_\alpha{}^{\beta_1}\Gamma_{10}\psi^{\beta_2} \\
&- \quad \frac{7}{32}e^{3\phi/4}F_{\alpha\beta}\Gamma^{\beta\gamma}\Gamma_{10}\psi_\gamma - \frac{7}{64}e^{3\phi/4}F_{\beta_1\beta_2}\Gamma^{\beta_1\beta_2}\Gamma_{10}\psi_\alpha \\
&+ \quad \frac{7}{32}e^{3\phi/4}F_{\alpha\beta}\Gamma_{10}\psi^\beta \\
&+ \quad \frac{1}{96}e^{-\phi/2}F_{\beta_1\beta_2\beta_3}\Gamma_\alpha{}^{\beta_1\beta_2\beta_3}\Gamma_{10}\lambda - \frac{3}{32}e^{-\phi/2}F_{\alpha\beta_1\beta_2}\Gamma^{\beta_1\beta_2}\Gamma_{10}\lambda \\
&+ \quad \frac{1}{96}e^{-\phi/2}F_{\beta_1\beta_2\beta_3}\Gamma_\alpha{}^{\beta_1\beta_2\beta_3\gamma}\Gamma_{10}\psi^\gamma + \frac{1}{32}e^{-\phi/2}F_{\beta_1\beta_2\beta_3}\Gamma^{\beta_1\beta_2\beta_3}\Gamma_{10}\psi_\alpha \\
&- \quad \frac{1}{32}e^{-\phi/2}F_{\beta_1\beta_2\beta_3}\Gamma_\alpha{}^{\beta_1\beta_2}\Gamma_{10}\psi^{\beta_3} - \frac{3}{32}e^{-\phi/2}F_{\alpha\beta_1\beta_2}\Gamma^{\beta_1\beta_2\gamma}\Gamma_{10}\psi_\gamma \\
&+ \quad \frac{3}{16}e^{-\phi/2}F_{\alpha\beta_1\beta_2}\Gamma^{\beta_1}\Gamma_{10}\psi^{\beta_2} \\
&- \quad \frac{1}{512}e^{\phi/4}F_{\beta_1\ldots\beta_4}\Gamma_\alpha{}^{\beta_1\ldots\beta_4}\lambda + \frac{5}{384}e^{\phi/4}F_{\alpha\beta_1\ldots\beta_3}\Gamma^{\beta_1\ldots\beta_3}\lambda \\
&- \quad \frac{1}{256}e^{\phi/4}F_{\beta_1\ldots\beta_4}\Gamma_\alpha{}^{\beta_1\ldots\beta_4\gamma}\psi^\gamma + \frac{5}{768}e^{\phi/4}F_{\beta_1\ldots\beta_4}\Gamma^{\beta_1\ldots\beta_4}\psi_\alpha \\
&+ \quad \frac{1}{64}e^{\phi/4}F_{\beta_1\ldots\beta_4}\Gamma_\alpha{}^{\beta_1\ldots\beta_3}\psi^{\beta_4} + \frac{5}{192}e^{\phi/4}F_{\alpha\beta_1\ldots\beta_3}\Gamma^{\beta_1\ldots\beta_3\gamma}\psi_\gamma \\
&- \quad \frac{5}{64}e^{\phi/4}F_{\alpha\beta_1\ldots\beta_3}\Gamma^{\beta_1\beta_2}\psi^{\beta_3} + \frac{1}{2}\partial_\alpha\phi\lambda \\
&+ \quad \frac{1}{32}e^{5\phi/4}m\Gamma_{\alpha\beta}\psi^\beta + \frac{9}{32}e^{5\phi/4}m\psi_\alpha + \frac{5}{64}e^{5\phi/4}m\Gamma_\alpha\lambda = 0\,.
\end{aligned} \tag{A.11}$$

A.5 Truncation on the supergravity side

As explained in Section 4.1 of the main text, the correspondence between the dynamics of the E_{10}-invariant sigma model and the dynamics of type IIA supergravity only works if a certain truncation is applied.

As dictated from the BKL analysis, the following truncations must be imposed on the equations of motion and Bianchi identities:

$$\partial_a(N\partial_0\phi) = \partial_a(N\omega_{0\,ab}) = \partial_a(N\omega_{a\,b0}) = \partial_a(N\partial_b\phi) = \partial_a(N\omega_{b\,cd}) = 0 \qquad \text{(A.12a)}$$

and

$$\begin{aligned} \partial_a\left(Ne^{3\phi/4}F_{0b}\right) = \partial_a\left(Ne^{-\phi/2}F_{0b_1b_2}\right) = \partial_a\left(Ne^{\phi/4}F_{0b_1b_2b_3}\right) &= 0\,, \\ \partial_a\left(Ne^{3\phi/4}F_{b_1b_2}\right) = \partial_a\left(Ne^{-\phi/2}F_{b_1b_2b_3}\right) = \partial_a\left(Ne^{\phi/4}F_{b_1b_2b_3b_4}\right) &= 0\,, \\ \partial_a\left(Ne^{5\phi/4}m\right) &= 0\,. \qquad \text{(A.12b)} \end{aligned}$$

Furthermore, as already indicated in (4.2), the spatial trace of the spin connection has to be set to zero

$$\omega_{b\,ba} = 0\,. \qquad \text{(A.12c)}$$

Equations (A.12) exhaust all truncations of the bosonic variables. As explained in the text, with these truncations the bosonic geodesic equations agree with the supergravity up to one term in the Einstein equation coming from the contribution to the Ricci tensor R_{ab} which is proportional to $\Omega_{ac\,d}\Omega_{bd\,c}$. We emphasize that there are no mismatches associated with the mass parameter m.

For the fermionic variables one also needs to apply appropriate truncations of spatial gradients. These turn out to be

$$N^{-1}\partial_a(N\lambda) = N^{-1/2}\partial_a(N^{1/2}\psi_b) = 0\,. \qquad \text{(A.13)}$$

With this choice of truncation the Dirac equation of the coset match exactly the fermionic equations of motion of supergravity if in addition the supersymmetric gauge

$$\psi_0 - \Gamma_0\Gamma^a\psi_a = 0 \qquad \text{(A.14)}$$

of (4.10) is adopted.

A.6 Reduction from $D = 11$

Our conventions for massless type IIA supergravity are consistent with the reduction of eleven-dimensional supergravity through the reduction ansatz and field redefinitions given in this section. This construction of massless type IIA was first carried out in [44–46]. In this section only, we will denote the $D = 11$ gravitino by Ψ_M.

The supersymmetry variation of the gravitino in eleven-dimensional supergravity is

$$\delta_{\varepsilon^{(11)}}\Psi^{(11)}_M = D^{(11)}_M\varepsilon^{(11)} + \frac{1}{288}\Big(\Gamma_M{}^{N_1\cdots N_4} - 8\delta_M^{[N_1}\Gamma^{N_2N_3N_4]}\Big)\varepsilon^{(11)}F^{(11)}_{N_1\cdots N_4}\,. \qquad \text{(A.15)}$$

We reduce this expression along x^{10} with the following ansatz for the eleven-dimensional vielbein:

$$E_M{}^A = \begin{pmatrix} e^{-\frac{1}{12}\phi} e_\mu{}^\alpha & e^{\frac{2}{3}\phi} A_\mu \\ 0 & e^{\frac{2}{3}\phi} \end{pmatrix}. \tag{A.16}$$

The four-form field strength is reduced as follows in curved indices

$$\begin{aligned} F^{(10)}_{\mu\nu\rho} &\equiv F^{(11)}_{\mu\nu\rho\tilde{1}0}, \\ F^{(10)}_{\mu\nu\rho\sigma} &\equiv F^{(11)}_{\mu\nu\rho\sigma} + 4A_{[\mu}F^{(10)}_{\nu\rho\sigma]}, \end{aligned} \tag{A.17}$$

where $\tilde{1}0$ denotes a curved index. The eleven-dimensional gravitino $\Psi^{(11)}_M$ splits into the ten-dimensional gravitino ψ_μ and the dilatino λ, according to the following field redefinitions

$$\begin{aligned} \Psi^{(11)}_\mu &= e^{-\frac{1}{24}\phi}\big(\psi_\mu - \frac{1}{12}\Gamma_\mu\lambda\big) + \frac{2}{3}e^{\frac{1}{24}\phi}\Gamma_{\tilde{1}0}A_\mu\lambda, \\ \Gamma^{\tilde{1}0}\Psi^{(11)}_{\tilde{1}0} &= \frac{2}{3}e^{\frac{1}{24}\phi}\lambda. \end{aligned} \tag{A.18}$$

We also rescale the supersymmetry parameter according to

$$\varepsilon \equiv e^{\frac{1}{24}\phi}\varepsilon^{(11)}. \tag{A.19}$$

B Details on the IIA level decomposition of $\mathfrak{e}_{10}$ and $\mathfrak{k}(\mathfrak{e}_{10})$

In this appendix we give all the details of the level deomposition of $\mathfrak{e}_{10}$ with respect to $\mathfrak{sl}(9,\mathbb{R})$, up to level $(\ell_1,\ell_2) = (4,1)$. In particular we give all the relevant $\mathfrak{e}_{10}$ commutators which are needed to compute the explicit expressions of the bosonic and fermionic equations of motion in Appendix C. Moreover, we give details on the spinor and and vector-spinor representations of $\mathfrak{k}(\mathfrak{e}_{10})$. Finally, we also extend the level decomposition up to level $(3,3)$, whose generator plays a role in the discussion in Section 6 in relation to the trombone symmetry and whose role in $\mathfrak{e}_{10}$ is studied in Appendix D.

B.1 Commutation relations for fields appearing in the dictionary

At level $(\ell_1,\ell_2) = (0,0)$ there is a copy of $\mathfrak{gl}(9,\mathbb{R}) = \mathfrak{sl}(9,\mathbb{R})\oplus\mathbb{R}$, as well as a scalar generator associated with the dilaton. Their relations are $(a, b = 1,\dots,9)$

$$\begin{aligned} &[K^a{}_b, K^c{}_d] = \delta^c_b K^a{}_d - \delta^a_d K^c{}_b\,, \qquad \langle K^a{}_b | K^c{}_d\rangle = \delta^a_d\delta^c_b - \delta^a_b\delta^c_d\,, \\ &[T, K^a{}_b] = 0\,, \qquad \langle T|T\rangle = \frac{1}{2}\,, \qquad \langle T|K^a{}_b\rangle = 0\,. \end{aligned} \tag{B.1}$$

Here, $\langle\cdot|\cdot\rangle$ is the invariant bilinear form. We define also the trace $K = \sum_{a=1}^{9} K^a{}_a$. For completeness

$$\begin{aligned} K &= 8h_1 + 16h_2 + 24h_3 + 32h_4 + 40h_5 + 48h_6 + 56h_7 + 37h_8 + 18h_9 + 27h_{10}\,, \\ T &= \frac{1}{2}h_1 + h_2 + \frac{3}{2}h_3 + 2h_4 + \frac{5}{2}h_5 + 3h_6 + \frac{7}{2}h_7 + \frac{25}{12}h_8 + \frac{2}{3}h_9 + \frac{23}{12}h_{10}\,. \end{aligned} \tag{B.2}$$

(ℓ_1, ℓ_2)	$\mathfrak{sl}(9,\mathbb{R})$ Dynkin labels	$\mathfrak{e}_{10}$ root α of lowest weight

$(3,3)$	$[1,0,0,0,0,0,0,1]$	$(0,1,2,3,4,5,6,4,3,3)$

Table 5: $\mathfrak{sl}(9,\mathbb{R})$ *level decomposition of* $\mathfrak{e}_{10}$ *with root vectors. All shown levels are complete. The very last entry is that of a mixed symmetry generator not studied for the dictionary of Table 2. Its possible relation to trombone gauging is discussed in Section 6 and in Appendix D.*

All objects transform as $\mathfrak{gl}(9,\mathbb{R})$ tensors in the obvious way. The T commutator relations are

$$\begin{aligned}
[T, E^{a_1}] &= \frac{3}{4} E^{a_1}\,, & [T, E^{a_1a_2}] &= -\frac{1}{2} E^{a_1a_2}\,, \\
[T, E^{a_1a_2a_3}] &= \frac{1}{4} E^{a_1a_2a_3}\,, & [T, E^{a_1\ldots a_5}] &= -\frac{1}{4} E^{a_1\ldots a_5}\,, \\
[T, E^{a_1\ldots a_6}] &= \frac{1}{2} E^{a_1\ldots a_6}\,, & [T, E^{a_1\ldots a_7}] &= -\frac{3}{4} E^{a_1\ldots a_7}\,, \\
[T, E^{a_1\ldots a_9}] &= -\frac{5}{4} E^{a_1\ldots a_9}\,, & & \\
\left[T, E^{a_0|a_1\ldots a_7}\right] &= 0\,, & [T, E^{a_1\ldots a_8}] &= 0\,.
\end{aligned} \tag{B.3}$$

The positive level generators are generated by the simple (fundamental) generators on levels $(0,1)$ and $(1,0)$ by

$$\begin{aligned}
[E^{a_1}, E^{a_2}] &= 0\,, & [E^{a_1a_2}, E^{a_3a_4}] &= 0\,, \\
[E^{a_1a_2}, E^{a_3}] &= E^{a_1a_2a_3}\,, & [E^{a_1a_2}, E^{a_3\ldots a_5}] &= E^{a_1\ldots a_5}\,, \\
[E^{a_1a_2}, E^{a_3\ldots a_7}] &= E^{a_1\ldots a_7}\,, & [E^{a_1a_2}, E^{a_3\ldots a_9}] &= E^{a_1\ldots a_9}\,, \\
[E^{a_1}, E^{a_2\ldots a_6}] &= E^{a_1\ldots a_6}\,, & [E^{a_0}, E^{a_1\ldots a_7}] &= E^{a_0|a_1\ldots a_7} + \frac{3}{2} E^{a_0a_1\ldots a_7}\,.
\end{aligned} \tag{B.4}$$

These defining relations imply for example

$$\begin{aligned}
[E^{a_1a_2a_3}, E^{a_4a_5a_6}] &= -E^{a_1\dots a_6}\,,\\
[E^{a_1a_2}, E^{a_3\dots a_8}] &= -2E^{[a_1|a_2]a_3\dots a_8} + E^{a_1\dots a_8}\,,\\
[E^{a_1a_2a_3}, E^{a_4\dots a_8}] &= -3E^{[a_1|a_2a_3]a_4\dots a_8} - \frac{1}{2}E^{a_1\dots a_8}\,,\\
[E^{a_1\dots a_5}, E^{a_6a_7a_8}] &= 5E^{[a_1|a_2\dots a_5]a_6a_7a_8} - \frac{1}{2}E^{a_1\dots a_8}\,,\\
[E^{a_1\dots a_6}, E^{a_7a_8}] &= -6E^{[a_1|a_2\dots a_6]a_7a_8} - E^{a_1\dots a_8}\,,\\
[E^{a_1\dots a_7}, E^{a_8}] &= -7E^{[a_1|a_2\dots a_7]a_8} + \frac{3}{2}E^{a_1\dots a_8}\,.
\end{aligned} \tag{B.5}$$

The Young symmetry on the dual graviton implies $E^{a_0|a_1\dots a_7} = 7E^{[a_1|a_2\dots a_7]a_0}$. The two irreducible representations on $(3,2)$ are projected onto via

$$\begin{aligned}
E^{a_1\dots a_8} &= \frac{2}{3}\left[E^{[a_1}, E^{a_2\dots a_8]}\right]\,, \quad E^{a_0|a_1\dots a_7} = \frac{7}{8}\left([E^{a_0}, E^{a_1\dots a_7}] + \left[E^{[a_1}, E^{a_2\dots a_7]a_0}\right]\right)\,,\\
E^{a_0|a_1\dots a_7} &= -\frac{7}{8}\left(\left[E^{a_0[a_1}, E^{a_2\dots a_7]}\right] + \left[E^{[a_1a_2}, E^{a_3\dots a_7]a_0}\right]\right)\,.
\end{aligned} \tag{B.6}$$

The definitions (B.4) are such that the normalisations are

$$\begin{aligned}
\langle E^{a_1\dots a_p}|F_{b_1\dots b_p}\rangle &= p!\,\delta^{a_1\dots a_p}_{b_1\dots b_p} && \Rightarrow \quad \langle E^{1\,\dots\,p}|F_{1\,\dots\,p}\rangle = 1 \quad (p\neq 8)\,,\\
\langle E^{a_1\dots a_8}|F_{b_1\dots b_8}\rangle &= \frac{1}{2}\cdot 8!\delta^{a_1\dots a_8}_{b_1\dots b_8} && \Rightarrow \quad \langle E^{1\,\dots\,8}|F_{1\,\dots\,8}\rangle = \frac{1}{2}\,,\\
\langle E^{a_0|a_1\dots a_7}|F_{b_0|b_1\dots b_7}\rangle &= \frac{7}{8}\cdot 7!\left(\delta^{a_0}_{b_0}\delta^{a_1\dots a_7}_{b_1\dots b_7} + \delta^{[a_1}_{b_0}\delta^{a_2\dots a_7]a_0}_{b_1\;\dots\dots\;b_7}\right)\,.
\end{aligned} \tag{B.7}$$

The additional factor of 2 in the normalisation of the 8-form is chosen such that all structure constants remain rational.

Defining the transposed generators via $F \equiv E^T$ as usual gives the following commutations relation between the form generators and their transposes:

$$\begin{aligned}
[E^a, F_b] &= -\frac{1}{8}\delta^a_b K + K^a{}_b + \frac{3}{2}\delta^a_b T\,,\\
[E^{a_1a_2}, F_{b_1b_2}] &= -\frac{1}{2}\delta^{a_1a_2}_{b_1b_2}K + 4\delta^{[a_1}_{[b_1}K^{a_2]}{}_{b_2]} - 2\delta^{a_1a_2}_{b_1b_2}T\,,\\
[E^{a_1a_2a_3}, F_{b_1b_2b_3}] &= -\frac{3}{8}\cdot 3!\,\delta^{a_1a_2a_3}_{b_1b_2b_3}K + 3\cdot 3!\,\delta^{[a_1a_2}_{[b_1b_2}K^{a_3]}{}_{b_3]} + 3\delta^{a_1a_2a_3}_{b_1b_2b_3}T\,,\\
[E^{a_1\dots a_5}, F_{b_1\dots b_5}] &= -\frac{5}{8}\cdot 5!\,\delta^{a_1\dots a_5}_{b_1\dots b_5}K + 5\cdot 5!\,\delta^{[a_1\dots a_4}_{[b_1\dots b_4}K^{a_5]}{}_{b_5]} - \frac{1}{2}\cdot 5!\,\delta^{a_1\dots a_5}_{b_1\dots b_5}T\,,\\
[E^{a_1\dots a_6}, F_{b_1\dots b_6}] &= -\frac{3}{4}\cdot 6!\,\delta^{a_1\dots a_6}_{b_1\dots b_6}K + 6\cdot 6!\,\delta^{[a_1\dots a_5}_{[b_1\dots b_5}K^{a_6]}{}_{b_6]} + 6!\,\delta^{a_1\dots a_6}_{b_1\dots b_6}T\,,\\
[E^{a_1\dots a_7}, F_{b_1\dots b_7}] &= -\frac{7}{8}\cdot 7!\,\delta^{a_1\dots a_7}_{b_1\dots b_7}K + 7\cdot 7!\,\delta^{[a_1\dots a_6}_{[b_1\dots b_6}K^{a_7]}{}_{b_7]} - \frac{3}{2}\cdot 7!\,\delta^{a_1\dots a_7}_{b_1\dots b_7}T\,,\\
[E^{a_1\dots a_9}, F_{b_1\dots b_9}] &= -\frac{9}{8}\cdot 9!\,\delta^{a_1\dots a_9}_{b_1\dots b_9}K + 9\cdot 9!\,\delta^{[a_1\dots a_8}_{[b_1\dots b_8}K^{a_9]}{}_{b_9]} - \frac{5}{2}\cdot 9!\,\delta^{a_1\dots a_9}_{b_1\dots b_9}T\,,\\
[E^{a_1\dots a_8}, F_{b_1\dots b_8}] &= -\frac{1}{2}\cdot 8!\,\delta^{a_1\dots a_8}_{b_1\dots b_8}K + 4\cdot 8!\,\delta^{[a_1\dots a_7}_{[b_1\dots b_7}K^{a_8]}{}_{b_8]}\,.
\end{aligned} \tag{B.8}$$

The commutator of the dual graviton generator $E^{a_0|a_1\ldots a_7}$ can be most conveniently written using a dummy tensor $X_{a_0|a_1\ldots a_7}$ as

$$\left[F_{b_0|b_1\ldots b_7}, X_{a_0|a_1\ldots a_7}E^{a_0|a_1\ldots a_7}\right] = 7!\left(X_{b_0|b_1\ldots b_7}K - X_{c|b_1\ldots b_7}K^c{}_{b_0} - 7X_{b_0|c[b_1\ldots b_6}K^c{}_{b_7]}\right). \tag{B.9}$$

The generators of different rank commute in the following non-trivial way:

$$\begin{aligned}
[E^a, F_{b_1b_2b_3}] &= 3\delta^a_{[b_1}F_{b_2b_3]}\,, & [E^{a_1a_2}, F_{b_1b_2b_3}] &= -6\delta^{a_1a_2}_{[b_1b_2}F_{b_3]}\,,\\
[E^{a_1a_2}, F_{b_1\ldots b_5}] &= -20\delta^{a_1a_2}_{[b_1b_2}F_{b_3b_4b_5]}\,, & [E^{a_1a_2a_3}, F_{b_1\ldots b_5}] &= 60\delta^{a_1a_2a_3}_{[b_1b_2b_3}F_{b_4b_5]}\,,\\
[E^a, F_{b_1\ldots b_6}] &= -6\delta^a_{[b_1}F_{b_2\ldots b_6]}\,, & [E^{a_1a_2a_3}, F_{b_1\ldots b_6}] &= 120\delta^{a_1a_2a_3}_{[b_1b_2b_3}F_{b_4b_5b_6]}\,,\\
[E^{a_1\ldots a_5}, F_{b_1\ldots b_6}] &= -6!\,\delta^{a_1\ldots a_5}_{[b_1\ldots b_5}F_{b_6]}\,, & [E^{a_1a_2}, F_{b_1\ldots b_7}] &= -7\cdot 6\delta^{a_1a_2}_{[b_1b_2}F_{b_3\ldots b_7]}\,,\\
[E^{a_1\ldots a_5}, F_{b_1\ldots b_7}] &= \frac{1}{2}\cdot 7!\,\delta^{a_1\ldots a_5}_{[b_1\ldots b_5}F_{b_6b_7]}\,, & [E^{a_1a_2}, F_{b_1\ldots b_9}] &= -9\cdot 8\delta^{a_1a_2}_{[b_1b_2}F_{b_3\ldots b_9]}\,,\\
[E^{a_1\ldots a_7}, F_{b_1\ldots b_9}] &= \frac{1}{2}\cdot 9!\,\delta^{a_1\ldots a_7}_{[b_1\ldots b_7}F_{b_8b_9]}\,.
\end{aligned} \tag{B.10}$$

Anticipating the geodesic equation we know that (B.10) describes all the couplings between the different forms occurring in the matter equations, so that for example the 9-form (=mass term) occurs only in the Bianchi identity for $F_{(2)}$ and in the eom of $F_{(3)}$, consistent with (A.4) and (A.5). The dilaton and Einstein equation are described by the couplings of equations (B.8) and (B.9).

The commutators with the dual dilaton are

$$\begin{aligned}
[E^a, F_{b_1\ldots b_8}] &= -6\delta^a_{[b_1}F_{b_2\ldots b_8]}\,, & [E^{a_1a_2}, F_{b_1\ldots b_8}] &= -4\cdot 7\delta^{a_1a_2}_{[b_1b_2}F_{b_3\ldots b_8]}\,,\\
[E^{a_1a_2a_3}, F_{b_1\ldots b_8}] &= 2\cdot 7\cdot 6\delta^{a_1a_2a_3}_{[b_1b_2b_3}F_{b_4\ldots b_8]}\,, & [E^{a_1\ldots a_5}, F_{b_1\ldots b_8}] &= 2\cdot 7\cdot 5!\,\delta^{a_1\ldots a_5}_{[b_1\ldots b_5}F_{b_6b_7b_8]}\,,\\
[E^{a_1\ldots a_6}, F_{b_1\ldots b_8}] &= 2\cdot 7!\,\delta^{a_1\ldots a_6}_{[b_1\ldots b_6}F_{b_7b_8]}\,, & [E^{a_1\ldots a_7}, F_{b_1\ldots b_8}] &= -6\cdot 7!\,\delta^{a_1\ldots a_7}_{[b_1\ldots b_7}F_{b_8]}\,,
\end{aligned} \tag{B.11}$$

whereas for the dual graviton one finds

$$\begin{aligned}
\left[E^a, F_{b_0|b_1\ldots b_7}\right] &= -\frac{7}{8}\left(\delta^a_{b_0}F_{b_1\ldots b_7} + \delta^a_{[b_1}F_{b_2\ldots b_7]b_0}\right)\,,\\
\left[E^{a_1a_2}, F_{b_0|b_1\ldots b_7}\right] &= \frac{21}{2}\left(\delta^{a_1a_2}_{b_0[b_1}F_{b_2\ldots b_7]} + \delta^{a_1a_2}_{[b_1b_2}F_{b_3\ldots b_7]b_0}\right)\,,\\
\left[E^{a_1a_2a_3}, F_{b_0|b_1\ldots b_7}\right] &= \frac{45\cdot 7}{4}\left(\delta^{a_1a_2a_3}_{b_0[b_1b_2}F_{b_3\ldots b_7]} + \delta^{a_1a_2a_3}_{[b_1b_2b_3}F_{b_4\ldots b_7]b_0}\right)\,,\\
\left[E^{a_1\ldots a_5}, F_{b_0|b_1\ldots b_7}\right] &= -\frac{5\cdot 7!}{16}\left(\delta^{a_1\ldots a_5}_{b_0[b_1\ldots b_4}F_{b_5\ldots b_7]} + \delta^{a_1\ldots a_5}_{[b_1\ldots b_5}F_{b_6b_7]b_0}\right)\,,\\
\left[E^{a_1\ldots a_6}, F_{b_0|b_1\ldots b_7}\right] &= \frac{3\cdot 7!}{4}\left(\delta^{a_1\ldots a_6}_{b_0[b_1\ldots b_5}F_{b_6b_7]} + \delta^{a_1\ldots a_6}_{[b_1\ldots b_6}F_{b_7]b_0}\right)\,,\\
\left[E^{a_1\ldots a_7}, F_{b_0|b_1\ldots b_7}\right] &= \frac{7\cdot 7!}{8}\left(\delta^{a_1\ldots a_7}_{b_0[b_1\ldots b_6}F_{b_7]} + \delta^{a_1\ldots a_7}_{b_1\ldots b_7}F_{b_0}\right)\,.
\end{aligned} \tag{B.12}$$

B.2 Spinor representations of $\mathfrak{k}(\mathfrak{e}_{10})$

For the E_{10} model to incorporate all low energy limits of M-theory in a single model, the fermionic representations used in (3.36) should not depend on the particular supergravity one wishes to study. Rather the unfaithful **320** and **32** representations of $\mathfrak{k}(\mathfrak{e}_{10})$ should be decomposed under a suitable subalgebra. Here, this subalgebra is $\mathfrak{so}(9) \subset \mathfrak{gl}(9,\mathbb{R})$ and this appendix provides the details of the action of the $\mathfrak{k}(\mathfrak{e}_{10})$ generators in this basis. When doing the following calculations we found the computer package GAMMA [71] useful.[22]

B.2.1 Dirac spinor

The result of writing the $K(E_{10})$ action on the Dirac spinor is (we recall the notation $M^{a_1a_2}$ for the level $(0,0)$ generator of $K(E_{10})$ from (3.17))

$$\begin{aligned}
M^{a_1a_2}\cdot\epsilon &= \frac{1}{2}\Gamma^{a_1a_2}\epsilon, & J^{a}_{(0,1)}\cdot\epsilon &= \frac{1}{2}\Gamma_{10}\Gamma^{a}\epsilon,\\
J^{a_1a_2}_{(1,0)}\cdot\epsilon &= \frac{1}{2}\Gamma_{10}\Gamma^{a_1a_2}\epsilon, & J^{a_1a_2a_3}_{(1,1)}\cdot\epsilon &= \frac{1}{2}\Gamma^{a_1a_2a_3}\epsilon,\\
J^{a_1\cdots a_5}_{(2,1)}\cdot\epsilon &= \frac{1}{2}\Gamma_{10}\Gamma^{a_1\cdots a_5}\epsilon, & J^{a_1\cdots a_6}_{(2,2)}\cdot\epsilon &= -\frac{1}{2}\Gamma^{a_1\cdots a_6}\epsilon,\\
J^{a_1\cdots a_7}_{(3,1)}\cdot\epsilon &= \frac{1}{2}\Gamma^{a_1\cdots a_7}\epsilon, & J^{a_0|a_1\cdots a_7}_{(3,2)}\cdot\epsilon &= \frac{7}{2}\Gamma_{10}\delta^{[a_1}_{a_0}\Gamma^{a_2\cdots a_7]}\epsilon,\\
J^{a_1\cdots a_8}_{(3,2)}\cdot\epsilon &= 0, & J^{a_1\cdots a_9}_{(4,1)}\cdot\epsilon &= \frac{1}{2}\Gamma_{10}\Gamma^{a_1\cdots a_9}\epsilon,
\end{aligned} \tag{B.13}$$

where the generators above levels $(0,1)$ and $(1,0)$ are defined through the lower levels as follows

$$\begin{aligned}
J^{a_1a_2a_3}_{(1,1)}\cdot\epsilon &:= \left[J^{[a_1a_2}_{(1,0)}, J^{a_3]}_{(0,1)}\right]\cdot\epsilon,\\
J^{a_1\cdots a_5}_{(2,1)}\cdot\epsilon &:= \left[J^{[a_1a_2}_{(1,0)}, J^{a_3a_4a_5]}_{(1,1)}\right]\cdot\epsilon,\\
J^{a_1\cdots a_6}_{(2,2)}\cdot\epsilon &:= \left[J^{[a_1}_{(1,1)}, J^{a_2\ldots a_6]}_{(1,1)}\right]\cdot\epsilon,\\
J^{a_1\cdots a_7}_{(3,1)}\cdot\epsilon &:= \left[J^{[a_1a_2}_{(1,0)}, J^{a_3\cdots a_7]}_{(2,1)}\right]\cdot\epsilon,\\
J^{a_0|a_1\cdots a_7}_{(3,2)}\cdot\epsilon &:= -\frac{7}{8}\Big(\left[J^{a_0}_{(0,1)}, J^{a_1\cdots a_7}_{(3,1)}\right]+\left[J^{[a_1}_{(0,1)}, J^{a_2\cdots a_7]a_0}_{(3,1)}\right]\Big)\cdot\epsilon,\\
J^{a_1\cdots a_8}_{(3,2)}\cdot\epsilon &:= \left[J^{[a_1a_2}_{(1,0)}, J^{a_3\cdots a_8]}_{(2,2)}\right]\cdot\epsilon,\\
J^{a_1\cdots a_9}_{(4,1)}\cdot\epsilon &:= \left[J^{[a_1a_2}_{(1,0)}, J^{a_3\cdots a_9]}_{(3,1)}\right]\cdot\epsilon.
\end{aligned} \tag{B.14}$$

We stress that this kind of construction is guaranteed to yield a consistent unfaithful representation of all of $\mathfrak{k}(\mathfrak{e}_{10})$ given that a few simple consistency conditions between the lowest level fundamental generators are satisfied [21]. That these conditions are satisfied here can be checked easily directly, but it also follows from the branching of the transformation rules given in [17, 18].

---

[22] We are grateful to Ulf Gran for generous help in modifying GAMMA to suit our needs.

B.2.2 Vector-spinor

By reduction of the transformation rules of [18, 19] one obtains that the fundamental $\mathfrak{k}(\mathfrak{e}_{10})$-generators act on the vector spinor representation as follows on the Ψ_{10} component

$$\begin{aligned}
J^{a}_{(0,1)}\cdot\Psi_{10} &= \frac{1}{2}\Gamma_{10}\Gamma^{a}\Psi_{10}+\Psi^{a}\\
J^{a_1a_2}_{(1,0)}\cdot\Psi_{10} &= \frac{1}{6}\Gamma_{10}\Gamma^{a_1a_2}\Psi_{10}+\frac{4}{3}\Gamma^{[a_1}\Psi^{a_2]}.
\end{aligned}$$

On the Ψ_a $(a=1,\ldots,9)$ component they act as

$$\begin{aligned}
J^{a}_{(0,1)}\cdot\Psi_{b} &= \frac{1}{2}\Gamma_{10}\Gamma^{a}\Psi_{b}-\delta^{a}_{b}\Psi_{10}\\
J^{a_1a_2}_{(1,0)}\cdot\Psi_{b} &= \frac{1}{2}\Gamma_{10}\Gamma^{a_1a_2}\Psi_{b}-\frac{4}{3}\Gamma_{10}\delta^{[a_1}_{b}\Psi^{a_2]}+\frac{2}{3}\Gamma_{10}\Gamma_{b}{}^{[a_1}\Psi^{a_2]}\\
&\quad+\frac{4}{3}\delta^{[a_1}_{b}\Gamma^{a_2]}\Psi_{10}-\frac{1}{3}\Gamma_{b}{}^{a_1a_2}\Psi_{10}.
\end{aligned}$$

The other levels action is then computed to be on Ψ_{10} as

$$\begin{aligned}
M^{a_1a_2}\cdot\Psi_{10} &= \frac{1}{2}\Gamma^{a_1a_2}\Psi_{10}\\
J^{a_1\cdots a_3}_{(1,1)}\cdot\Psi_{10} &= \frac{1}{2}\Gamma^{a_1\cdots a_3}\Psi_{10}-\Gamma_{10}\Gamma^{[a_1a_2}\Psi^{a_3]}\\
J^{a_1\cdots a_5}_{(2,1)}\cdot\Psi_{10} &= -\frac{1}{6}\Gamma_{10}\Gamma^{a_1\cdots a_5}\Psi_{10}-\frac{5}{3}\Gamma^{[a_1\cdots a_4}\Psi^{a_5]}\\
J^{a_1\cdots a_6}_{(2,2)}\cdot\Psi_{10} &= -\frac{1}{2}\Gamma^{a_1\cdots a_6}\Psi_{10}-4\Gamma_{10}\Gamma^{[a_1\cdots a_5}\Psi^{a_6]}\\
J^{a_1\cdots a_7}_{(3,1)}\cdot\Psi_{10} &= -\frac{3}{2}\Gamma^{a_1\cdots a_7}\Psi_{10}+7\Gamma_{10}\Gamma^{[a_1\cdots a_6}\Psi^{a_7]}\\
J^{a_1\cdots a_8}_{(3,2)}\cdot\Psi_{10} &= -\frac{4}{3}\Gamma_{10}\Gamma^{a_1\cdots a_8}\Psi_{10}-\frac{32}{3}\Gamma^{[a_1\cdots a_7}\Psi^{a_8]}\\
J^{a_0|a_1\cdots a_7}_{(3,2)}\cdot\Psi_{10} &= -\frac{7}{2}\Gamma_{10}\delta^{[a_1}_{a_0}\Gamma^{a_2\cdots a_7]}\Psi_{10}\\
J^{a_1\cdots a_9}_{(4,1)}\cdot\Psi_{10} &= \frac{9}{2}\Gamma_{10}\Gamma^{a_1\cdots a_9}\Psi_{10}-15\Gamma^{[a_1\cdots a_8}\Psi^{a_9]}.
\end{aligned}\tag{B.15}$$

On Ψ_a we obtain similarly

$$
\begin{aligned}
M^{a_1a_2}\cdot\Psi_b &= \frac{1}{2}\Gamma^{a_1a_2}\Psi_b + 2\delta_b^{[a_1}\Psi^{a_2]} \\
J_{(1,1)}^{a_1\cdots a_3}\cdot\Psi_b &= \frac{1}{2}\Gamma^{a_1\cdots a_3}\Psi_b + 4\delta_b^{[a_1}\Gamma^{a_2}\Psi^{a_3]} - \Gamma_b{}^{[a_1a_2}\Psi^{a_3]} \\
J_{(2,1)}^{a_1\cdots a_5}\cdot\Psi_b &= \frac{1}{2}\Gamma_{10}\Gamma^{a_1\cdots a_5}\Psi_b + \frac{20}{3}\Gamma_{10}\delta_b^{[a_1}\Gamma^{a_2\cdots a_4}\Psi^{a_5]} - \frac{10}{3}\Gamma_{10}\Gamma_b{}^{[a_1\cdots a_4}\Psi^{a_5]} \\
&\quad + \frac{5}{3}\delta_b^{[a_1}\Gamma^{a_2\cdots a_5]}\Psi_{10} - \frac{2}{3}\Gamma_b{}^{a_1\cdots a_5}\Psi_{10} \\
J_{(2,2)}^{a_1\cdots a_6}\cdot\Psi_b &= -\frac{1}{2}\Gamma^{a_1\cdots a_6}\Psi_b + 10\delta_b^{[a_1}\Gamma^{a_2\cdots a_5}\Psi^{a_6]} - 4\Gamma_b{}^{[a_1\cdots a_5}\Psi^{a_6]} \\
J_{(3,1)}^{a_1\cdots a_7}\cdot\Psi_b &= \frac{1}{2}\Gamma^{a_1\cdots a_7}\Psi_b - 7\Gamma_b{}^{[a_1\cdots a_6}\Psi^{a_7]} - 2\Gamma_{10}\Gamma_b{}^{a_1\cdots a_7}\Psi_{10} \\
J_{(3,2)}^{a_1\cdots a_8}\cdot\Psi_b &= -\frac{4}{3}\Gamma_{10}\Gamma_b{}^{[a_1\cdots a_7}\Psi^{a_8]} - \frac{28}{3}\Gamma_{10}\delta_b^{[a_1}\Gamma^{a_2\cdots a_7}\Psi^{a_8]} \\
&\quad - \frac{4}{3}\Gamma_b{}^{a_1\cdots a_8}\Psi_{10} + \frac{4}{3}\delta_b^{[a_1}\Gamma^{a_2\cdots a_8]}\Psi_{10} \\
J_{(3,2)}^{a_0|a_1\cdots a_7}\cdot\Psi_b &= \frac{7}{2}\Gamma_{10}\delta_{a_0}^{[a_1}\Gamma^{a_2\cdots a_7]}\Psi_b - \frac{21}{2}\Gamma_{10}\delta_b^{[a_1}\Gamma_{a_0}{}^{a_2\cdots a_6}\Psi^{a_7]} - \frac{49}{4}\Gamma_{10}\delta_b^{a_0}\Gamma^{[a_1\cdots a_6}\Psi^{a_7]} \\
&\quad + 42\Gamma_{10}\delta_{a_0}^{[a_1}\Gamma_b{}^{a_2\cdots a_6}\Psi^{a_7]} - 7\delta_{a_0}^{[a_1}\Gamma_b{}^{a_2\cdots a_7]}\Psi_{10} \\
&\quad + \frac{7}{4}\Big(\Gamma_{10}\Gamma_b{}^{a_0[a_1\cdots a_6}\Psi^{a_7]} - \Gamma_{10}\delta_b^{[a_1}\Gamma^{a_2\cdots a_7]}\Psi^{a_0} \\
&\qquad + \Gamma_{10}\Gamma_b{}^{a_1\cdots a_7}\Psi^{a_0} + \delta_b^{[a_1}\Gamma^{a_2\cdots a_7]a_0}\Psi_{10} + \delta_b^{a_0}\Gamma^{a_1\cdots a_7}\Psi_{10}\Big) \\
J_{(4,1)}^{a_1\cdots a_9}\cdot\Psi_b &= \frac{1}{2}\Gamma_{10}\Gamma^{a_1\cdots a_9}\Psi_b - 12\Gamma_{10}\Gamma_b{}^{[a_1\cdots a_8}\Psi^{a_9]} \\
&\quad - 24\Gamma_{10}\delta_b^{[a_1}\Gamma^{a_2\cdots a_8}\Psi^{a_9]} - 9\delta_b^{[a_1}\Gamma^{a_2\cdots a_9]}\Psi_{10}.
\end{aligned}
\tag{B.16}
$$

We note that the mixed symmetry generator at level $(3,2)$ indeed satisfies

$$
J_{(3,2)}^{[a_0|a_1\cdots a_7]}\cdot\Psi_b = 0 \tag{B.17}
$$

as desired.

C Equations of motion of the $E_{10}/K(E_{10})$ coset model

Using all the explicit commutators and representations of the Appendix B, we can now write out the bosonic and fermionic equations of motion in their full glory.

C.1 Bosonic equations of motion

The level zero equations of motion read

$$\begin{aligned}
\partial_t^2\phi &= e^{3\phi/2}P_aP_a - 2e^{-\phi}P_{a_1a_2}P_{a_1a_2} + \frac{1}{3}e^{\phi/2}P_{a_1a_2a_3}P_{a_1a_2a_3} \\
&\quad -\frac{2}{5!}e^{-\phi/2}P_{a_1\dots a_5}P_{a_1\dots a_5} + \frac{4}{6!}e^{\phi}P_{a_1\dots a_6}P_{a_1\dots a_6} \\
&\quad -\frac{6}{7!}e^{-3\phi/2}P_{a_1\dots a_7}P_{a_1\dots a_7} - \frac{10}{9!}e^{-5\phi/2}P_{a_1\dots a_9}P_{a_1\dots a_9} \qquad \text{(C.1a)} \\
D^{(0)}p_{ab} &= -\frac{1}{4}e^{3\phi/2}\delta_{ab}P_cP_c + 2e^{3\phi/2}P_aP_b \\
&\quad -\frac{1}{4}e^{-\phi}\delta_{ab}P_{cd}P_{cd} + 2e^{-\phi}P_{ca}P_{cb} \\
&\quad -\frac{1}{8}e^{\phi/2}\delta_{ab}P_{c_1c_2c_3}P_{c_1c_2c_3} + e^{\phi/2}P_{ac_1c_2}P_{bc_1c_2} \\
&\quad -\frac{1}{4\cdot 4!}e^{-\phi/2}\delta_{ab}P_{c_1\cdots c_5}P_{c_1\cdots c_5} + \frac{2}{4!}e^{-\phi/2}P_{ac_1\cdots c_4}P_{bc_1\cdots c_4} \\
&\quad -\frac{3}{2\cdot 6!}e^{\phi}\delta_{ab}P_{c_1\cdots c_6}P_{c_1\cdots c_6} + \frac{2}{5!}e^{\phi}P_{ac_1\cdots c_5}P_{bc_1\cdots c_5} \\
&\quad -\frac{1}{4\cdot 6!}e^{-3\phi/2}\delta_{ab}P_{c_1\cdots c_7}P_{c_1\cdots c_7} + \frac{2}{6!}e^{-3\phi/2}P_{ac_1\cdots c_6}P_{bc_1\cdots c_6} \\
&\quad -\frac{1}{8!}\delta_{ab}P_{c_1\cdots c_8}P_{c_1\cdots c_8} + \frac{1}{7!}P_{ac_1\cdots c_7}P_{bc_1\cdots c_7} \\
&\quad +\frac{1}{4\cdot 8!}\big(-\delta_{ab}P_{c_0|c_1\cdots c_7}P_{c_0|c_1\cdots c_7} + P_{a|c_1\cdots c_7}P_{b|c_1\cdots c_7} \\
&\quad +7P_{c_0|c_1\cdots c_6a}P_{c_0|c_1\cdots c_6b}\big) \\
&\quad -\frac{1}{4\cdot 8!}e^{-5\phi/2}\delta_{ab}P_{c_1\cdots c_9} + \frac{2}{8!}e^{-5\phi/2}P_{ac_1\cdots c_8}P_{bc_1\cdots c_8}\,. \qquad \text{(C.1b)}
\end{aligned}$$

For the higher level fields the equations of motion become

$$\begin{aligned}
D^{(0)}(e^{3\phi/2}P_a) &= -e^{\phi/2}P_{ac_1c_2}P_{c_1c_2} + \frac{2}{5!}e^{\phi}P_{ac_1\dots c_5}P_{c_1\dots c_5} + \frac{12}{8!}P_{ac_1\dots c_7}P_{c_1\dots c_7} \\
&\quad -\frac{7}{4\cdot 8!}(P_{c_1|ac_2\dots c_7}P_{c_1\dots c_7} + P_{a|c_1\dots c_7}P_{c_1\dots c_7})\,, \qquad \text{(C.2a)} \\
D^{(0)}(e^{-\phi}P_{a_1a_2}) &= 2e^{\phi/2}P_{a_1a_2c}P_c + \frac{1}{3}e^{-\phi/2}P_{a_1a_2c_1c_2c_3}P_{c_1c_2c_3} \\
&\quad +\frac{2}{5!}e^{-3\phi/2}P_{a_1a_2c_1\dots c_5}P_{c_1\dots c_5} + \frac{2}{7!}e^{-5\phi/2}P_{a_1a_2c_1\dots c_7}P_{c_1\dots c_7} \\
&\quad +\frac{1}{6!}P_{a_1a_2c_1\dots c_6}P_{c_1\dots c_6} \\
&\quad +\frac{3}{8\cdot 6!}(P_{c_1|a_1a_2c_2\dots c_6}P_{c_1\dots c_6} + P_{a_1|a_2c_1\dots c_6}P_{c_1\dots c_6})\,, \qquad \text{(C.2b)} \\
D^{(0)}(e^{\phi/2}P_{a_1a_2a_3}) &= -e^{-\phi/2}P_{a_1a_2a_3c_1c_2}P_{c_1c_2} - \frac{1}{3}e^{\phi}P_{a_1a_2a_3c_1c_2c_3}P_{c_1c_2c_3} \\
&\quad -\frac{1}{2\cdot 5!}P_{a_1a_2a_3c_1\dots c_5}P_{c_1\dots c_5}
\end{aligned}$$

$$\begin{aligned}
& & +\frac{1}{256}(P_{c_1|a_1a_2a_3c_2\ldots c_5}P_{c_1\ldots c_5} + P_{a_1|a_2a_3c_1\ldots c_5}P_{c_1\ldots c_5})\,, \qquad \text{(C.2c)}\\
D^{(0)}(e^{-\phi/2}P_{a_1\ldots a_5}) &=& 2e^{\phi}P_{a_1\ldots a_5c}P_c - e^{-3\phi/2}P_{a_1\ldots a_4c_1c_2}P_{c_1c_2}\\
& & -\frac{1}{12}P_{a_1\ldots a_5c_1c_2c_3}P_{c_1c_2c_3}\\
& & +\frac{1}{28}(P_{c_1|a_1\ldots a_5c_2c_3}P_{c_1\ldots c_3} + P_{a_1|a_2\ldots a_5c_1\ldots c_3}P_{c_1\ldots c_3})\,, \qquad \text{(C.2d)}\\
D^{(0)}(e^{\phi}P_{a_1\ldots a_6}) &=& -\frac{1}{2}P_{a_1\ldots a_6c_1c_2}P_{c_1c_2}\\
& & -\frac{3}{16}(P_{c_1|a_1\ldots a_6c_2}P_{c_1c_2} + P_{a_1|a_2\ldots a_6c_1c_2}P_{c_1c_2})\,, \qquad \text{(C.2e)}\\
D^{(0)}(e^{-3\phi/2}P_{a_1\ldots a_7}) &=& -e^{-5\phi/2}P_{a_1\ldots a_7c_1c_2}P_{c_1c_2} + \frac{3}{2}P_{a_1\ldots a_7c}P_c\\
& & -\frac{7}{32}(P_{c|a_1\ldots a_7}P_c + P_{a_1|a_2\ldots a_7c}P_c)\,, \qquad \text{(C.2f)}\\
D^{(0)}(e^{-5\phi/2}P_{a_1\ldots a_9}) &=& 0\,, \qquad \text{(C.2g)}\\
D^{(0)}P_{a_1\ldots a_8} &=& 0\,, \qquad \text{(C.2h)}\\
D^{(0)}P_{a_0|a_1\ldots a_7} &=& 0\,. \qquad \text{(C.2i)}
\end{aligned}$$

C.2 Fermionic equations of motion

The fermionic sector of the E_{10}-invariant Lagrangian involves a Dirac-type kinetic term for the 320-dimensional vector-spinor representation Ψ of $\mathfrak{k}(\mathfrak{e}_{10})$ which was given in (3.36). The resulting Dirac equation can be evaluated for both the Ψ_a and the Ψ_{10} components as in (3.38) using the expressions for the $K(E_{10})$ action which were derived in Appendix B.2.

The result for the Ψ_{10} component up to level $(4,1)$ is

$$\begin{aligned}
0 &=& \partial_t\Psi_{10} - \frac{1}{4}q_{a_1a_2}\Gamma^{a_1a_2}\Psi_{10}\\
&-& \frac{1}{2}e^{3\phi/4}P_a\Gamma_{10}\Gamma^a\Psi_{10} - e^{3\phi/4}P_a\Psi^a\\
&-& \frac{1}{12}e^{-\phi/2}P_{a_1a_2}\Gamma_{10}\Gamma^{a_1a_2}\Psi_{10} - \frac{2}{3}e^{-\phi/2}P_{a_1a_2}\Gamma^{a_1}\Psi^{a_2}\\
&-& \frac{1}{12}e^{\phi/4}P_{a_1a_2a_3}\Gamma^{a_1\cdots a_3}\Psi_{10} + \frac{1}{6}e^{\phi/4}P_{a_1a_2a_3}\Gamma_{10}\Gamma^{a_1a_2}\Psi^{a_3}\\
&+& \frac{1}{6!}e^{-\phi/4}P_{a_1\cdots a_5}\Gamma_{10}\Gamma^{a_1\cdots a_5}\Psi_{10} + \frac{1}{3\cdot 4!}e^{-\phi/4}P_{a_1\cdots a_5}\Gamma^{a_1\cdots a_4}\Psi^{a_5}\\
&+& \frac{1}{2\cdot 6!}e^{\phi/2}P_{a_1\cdots a_6}\Gamma^{a_1\cdots a_6}\Psi_{10} + \frac{1}{180}e^{\phi/2}P_{a_1\cdots a_6}\Gamma_{10}\Gamma^{a_1\cdots a_5}\Psi^{a_6}\\
&+& \frac{3}{2\cdot 7!}e^{-3\phi/4}P_{a_1\cdots a_7}\Gamma^{a_1\cdots a_7}\Psi_{10} - \frac{1}{6!}e^{-3\phi/4}P_{a_1\cdots a_7}\Gamma_{10}\Gamma^{a_1\cdots a_6}\Psi^{a_7}\\
&+& \frac{4}{3\cdot 8!}P_{a_1\cdots a_8}\Gamma_{10}\Gamma^{a_1\cdots a_8}\Psi_{10} + \frac{4}{3\cdot 7!}P_{a_1\cdots a_8}\Gamma^{a_1\cdots a_7}\Psi^{a_8}
\end{aligned}$$

$$
\begin{aligned}
&+ \quad \frac{7}{2\cdot 8!} P_{c|ca_1\cdots a_6}\Gamma_{10}\Gamma^{a_1\cdots a_6}\Psi_{10} \\
&- \quad \frac{1}{2\cdot 8!} e^{-5\phi/4} P_{a_1\cdots a_9}\Gamma_{10}\Gamma^{a_1\cdots a_9}\Psi_{10} + \frac{15}{9!} e^{-5\phi/4} P_{a_1\cdots a_9}\Gamma^{a_1\cdots a_8}\Psi^{a_9} + \ldots\,,
\end{aligned}
\tag{C.3}
$$

and is related to the dilatino equation of motion in the body of the article.

For the gravitino component Ψ_a one finds similarly

$$
\begin{aligned}
0 \quad = \quad & \partial_t \Psi_a - \frac{1}{4} q_{b_1b_2}\Gamma^{b_1b_2}\Psi_a - q_{ab}\Psi_b \\
- \quad & \frac{1}{2} e^{3\phi/4} P_b \Gamma_{10}\Gamma^b \Psi_a + e^{3\phi/4} P_a \Psi_{10} \\
- \quad & \frac{1}{4} e^{-\phi/2} P_{b_1b_2}\Gamma_{10}\Gamma^{b_1b_2}\Psi_a + \frac{2}{3} e^{-\phi/2} P_{ab}\Gamma_{10}\Psi^b - \frac{1}{3} e^{-\phi/2} P_{b_1b_2}\Gamma_{10}\Gamma_a{}^{b_1}\Psi^{b_2} \\
& -\frac{2}{3} e^{-\phi/2} P_{ab}\Gamma^b\Psi_{10} + \frac{1}{6} e^{-\phi/2} P_{b_1b_1}\Gamma_a{}^{b_1b_2}\Psi_{10} \\
- \quad & \frac{1}{12} e^{\phi/4} P_{b_1b_2b_3}\Gamma^{b_1\cdots b_3}\Psi_a - \frac{2}{3} e^{\phi/4} P_{ab_1b_2}\Gamma^{b_1}\Psi^{b_2} + \frac{1}{6} e^{\phi/4} P_{b_1b_2b_3}\Gamma_a{}^{b_1b_2}\Psi^{b_3} \\
- \quad & \frac{1}{2\cdot 5!} e^{-\phi/4} P_{b_1\cdots b_5}\Gamma_{10}\Gamma^{b_1\cdots b_5}\Psi_a - \frac{1}{18} e^{-\phi/4} P_{ab_1\cdots b_4}\Gamma_{10}\Gamma^{b_1\cdots b_3}\Psi^{b_4} \\
& +\frac{1}{36} e^{-\phi/4} P_{b_1\cdots b_5}\Gamma_{10}\Gamma_a{}^{b_1\cdots b_4}\Psi^{b_5} - \frac{1}{3\cdot 4!} e^{-\phi/4} P_{ab_1\cdots b_4}\Gamma^{b_1\cdots b_4}\Psi_{10} \\
& +\frac{2}{3\cdot 5!} e^{-\phi/4} P_{b_1\cdots b_5}\Gamma_a{}^{b_1\cdots b_5}\Psi_{10} \\
+ \quad & \frac{1}{2\cdot 6!} e^{\phi/2} P_{b_1\cdots b_6}\Gamma^{b_1\cdots b_6}\Psi_a - \frac{1}{3\cdot 4!} e^{\phi/2} P_{ab_1\cdots b_5}\Gamma^{b_1\cdots b_4}\Psi^{b_5} + \frac{4}{6!} e^{\phi/2} P_{b_1\cdots b_6}\Gamma_a{}^{b_1\cdots b_5}\Psi^{b_6} \\
- \quad & \frac{1}{2\cdot 7!} e^{-3\phi/4} P_{b_1\cdots b_7}\Gamma^{b_1\cdots b_7}\Psi_a + \frac{1}{6!} e^{-3\phi/4} P_{b_1\cdots b_7}\Gamma_a{}^{b_1\cdots b_6}\Psi^{b_7} \\
& +\frac{2}{7!} e^{-3\phi/4} P_{b_1\cdots b_7}\Gamma_{10}\Gamma_a{}^{b_1\cdots b_7}\Psi_{10} \\
+ \quad & \frac{1}{6\cdot 7!} P_{b_1\cdots b_8}\Gamma_{10}\Gamma_a{}^{b_1\cdots b_7}\Psi^{b_8} + \frac{1}{6\cdot 6!} P_{ab_1\cdots b_7}\Gamma_{10}\Gamma^{b_1\cdots b_6}\Psi^{b_7} \\
& +\frac{1}{6\cdot 7!} P_{b_1\cdots b_8}\Gamma_a{}^{b_1\cdots b_8}\Psi_{10} - \frac{1}{6\cdot 7!} P_{ab_1\cdots b_7}\Gamma^{b_1\cdots b_7}\Psi_{10} \\
- \quad & \frac{7}{2\cdot 8!} P_{c|cb_1\cdots b_6}\Gamma_{10}\Gamma^{b_1\cdots b_6}\Psi_a + \frac{21}{2\cdot 8!} P_{b_0|ab_1\cdots b_6}\Gamma_{10}\Gamma^{b_0b_1\cdots b_5}\Psi^{b_6} \\
& +\frac{49}{4\cdot 8!} P_{a|b_1\cdots b_7}\Gamma_{10}\Gamma^{b_1\cdots b_6}\Psi^{b_7} - \frac{42}{8!} P_{c|cb_1\cdots b_6}\Gamma_{10}\Gamma_a{}^{b_1\cdots b_5}\Psi^{b_6} + \frac{7}{8!} P_{c|cb_1\cdots b_6}\Gamma_a{}^{b_1\cdots b_6}\Psi_{10} \\
& -\frac{7}{4\cdot 8!} P_{b_0|b_1\cdots c_7}\Gamma_{10}\Gamma_a{}^{b_0b_1\cdots b_6}\Psi^{b_7} + \frac{7}{4\cdot 8!} P_{b_0|ab_1\cdots b_6}\Gamma_{10}\Gamma^{b_1\cdots b_6}\Psi^{b_0} \\
& -\frac{7}{4\cdot 8!} P_{b_0|b_1\cdots b_7}\Gamma_{10}\Gamma_a{}^{b_1\cdots b_7}\Psi^{b_0} - \frac{7}{4\cdot 8!} P_{b_0|ab_1\cdots b_6}\Gamma^{b_0b_1\cdots b_6}\Psi_{10} \\
& -\frac{7}{4\cdot 8!} P_{a|b_1\cdots b_7}\Gamma^{b_1\cdots b_7}\Psi_{10} \\
- \quad & \frac{1}{2\cdot 9!} e^{-5\phi/4} P_{b_1\cdots b_9}\Gamma_{10}\Gamma^{b_1\cdots b_9}\Psi_a + \frac{12}{9!} e^{-5\phi/4} P_{b_1\cdots b_9}\Gamma_{10}\Gamma_a{}^{b_1\cdots b_8}\Psi^{b_9} \\
& +\frac{24}{9!} e^{-5\phi/4} P_{ab_1\cdots b_8}\Gamma_{10}\Gamma^{b_1\cdots b_7}\Psi^{b_8} + \frac{1}{8!} e^{-5\phi/4} P_{ab_1\cdots b_8}\Gamma^{b_1\cdots b_8}\Psi_{10} + \ldots\,.
\end{aligned}
\tag{C.4}
$$

C.3 Supersymmetry variation

In the same fashion, the supersymmetry variation given in (3.39) can be written explicitly as

$$\begin{aligned}
\delta\Psi_t &= \partial_t\epsilon - \frac{1}{4}q_{a_1a_2}\Gamma^{a_1a_2}\epsilon - \frac{1}{2}e^{3\phi/4}P_a\Gamma_{10}\Gamma^a\epsilon - \frac{1}{4}e^{-\phi/2}P_{a_1a_2}\Gamma_{10}\Gamma^{a_1a_2}\epsilon \\
&- \frac{1}{2\cdot 3!}e^{\phi/4}P_{a_1a_2a_3}\Gamma^{a_1a_2a_3}\epsilon - \frac{1}{2\cdot 5!}e^{-\phi/4}P_{a_1\cdots a_5}\Gamma_{10}\Gamma^{a_1\cdots a_5}\epsilon + \frac{1}{2\cdot 6!}e^{\phi/2}P_{a_1\cdots a_6}\Gamma^{a_1\cdots a_6}\epsilon \\
&- \frac{1}{2\cdot 7!}e^{-3\phi/4}P_{a_1\cdots a_7}\Gamma^{a_1\cdots a_7}\epsilon - \frac{7}{2\cdot 8!}P_{c|ca_1\cdots a_6}\Gamma_{10}\Gamma^{a_1\cdots a_6}\epsilon \\
&- \frac{1}{2\cdot 9!}e^{-5\phi/4}P_{a_1\cdots a_9}\Gamma_{10}\Gamma^{a_1\cdots a_9}\epsilon + \cdots
\end{aligned} \tag{C.5}$$

D The trombone generator

The generator which was conjectured in [42] to be related to deformations of supergravity involving a gauging of the on-shell trombone symmetry appears in this case on level $(3,3)$ and has the index structure $E^{a_0|a_1\ldots a_8}$ with vanishing totally antisymmetric part. As noted in the text, it descends from the usual dual graviton in $D=11$. From Table 5 in Appendix B.1 it can be seen that the conjectured trombone gauging generator arises from a generator of E_9 since its first root entry is zero. More precisely, in current algebra language it is the affine level one copy of the lowest root of E_8.

D.1 Appearance in the coset equations of motion

We now work out the commutation relations of this level $(3,3)$ generator without entering into all the details. It can be defined as arising from a commutator of level $(0,1)$ and $(3,2)$ via

$$\left[E^{a_0}, E^{a_1\ldots a_8}\right] = E^{a_0|a_1\ldots a_8}\,. \tag{D.1}$$

This definition implies that also $\left[E^{a_0|a_1\ldots a_7}, E^{a_8}\right]$ has a contribution to the level $(3,3)$ generator. This coupling is related to a Lorentz covariantization and we will not study it in detail here. The generator $E^{a_0|a_1\ldots a_8}$ transforms in a hook representation of $SL(9,\mathbb{R})$ and carries charge $3/4$ under the dilaton generator T

$$E^{[a_0|a_1\ldots a_8]} = 0\,, \quad \left[T, E^{a_0|a_1\ldots a_8}\right] = \frac{3}{4}E^{a_0|a_1\ldots a_8}\,. \tag{D.2}$$

From the commutation relations of Appendix B.1 and (D.1) one deduces that $E^{a_0|a_1\ldots a_8}$ has non-vanishing commutation relations only with the negative level F-type generators as follows

$$\begin{aligned}
\left[E^{a_0|a_1\ldots a_8}, F_{b_1b_2b_3}\right] &= -7\cdot 12\left(\delta^{a_0[a_1a_2}_{b_1b_2b_3}E^{a_3\ldots a_8]} - \delta^{[a_1a_2a_3}_{b_1b_2b_3}E^{a_3\ldots a_8]a_0}\right)\\
\left[E^{a_0|a_1\ldots a_8}, F_{b_1\ldots b_6}\right] &= 2\cdot 7!\left(\delta^{a_0[a_1\ldots a_5}_{b_1\ldots b_6}E^{a_6a_7a_8]} - \delta^{[a_1\ldots a_6}_{b_1\ldots b_6}E^{a_7a_8]a_0}\right)\\
\left[E^{a_0|a_1\ldots a_8}, F_b\right] &= \delta^{a_0}_b E^{a_1\ldots a_8} - \delta^{[a_1}_b E^{a_2\ldots a_8]a_0}\,,\\
\left[E^{a_0|a_1\ldots a_8}, F_{b_1\ldots b_8}\right] &= \frac{1}{2}\cdot 8!\left(\delta^{a_1\ldots a_8}_{b_1\ldots b_8}E^{a_0} - \delta^{a_0[a_1\ldots a_7}_{b_1\ldots b_8}E^{a_8]}\right)\,,
\end{aligned}\tag{D.3}$$

and of course with its own dual $F_{b_0|b_1\ldots b_8}$ and $F_{b_0|b_1\ldots b_7}$. We introduce the contribution of this generator to the Maurer–Cartan form (3.43) as

$$\mathcal{P} \to \mathcal{P} + \frac{1}{9!}e^{3\phi/4}P_{a_0|a_1\ldots a_8}S^{a_0|a_1\ldots a_8}\,. \tag{D.4}$$

The commutators (D.3) imply that the geodesic equations (C.1) and (C.2) get additional contributions in the following way

$$\begin{aligned}
D^{(0)}(e^{3\phi/2}P_a) &= \frac{1}{6\cdot 8!}e^{3\phi/2}P_{a|c_1\ldots c_8}P_{c_1\ldots c_8} + \ldots\,,\\
D^{(0)}(e^{\phi/2}P_{a_1a_2a_3}) &= \frac{1}{2\cdot 6!}e^{3\phi/2}P_{c_1|c_2\ldots c_6a_1a_2a_3}P_{c_1\ldots c_6} + \ldots\,,\\
D^{(0)}(e^{\phi}P_{a_1\ldots a_6}) &= -\frac{1}{24}e^{3\phi/2}P_{c_1|c_2c_3a_1\ldots a_6}P_{c_1c_2c_3} + \ldots
\end{aligned}\tag{D.5}$$

and an additional contribution in the dual dilaton equation and dual graviton equations. In addition, there are contributions to the Einstein equation and scalar equations of the form

$$\begin{aligned}
D^{(0)}p_{ab} &= \frac{1}{4\cdot 9!}e^{3\phi/2}(P_{a|c_1\ldots c_8}P_{b|c_1\ldots c_8} + 8P_{c_0|c_1\ldots c_7a}P_{c_0|c_1\ldots c_7b}\\
&\qquad\qquad - \delta_{ab}P_{c_0|c_1\ldots c_8}P_{c_0|c_1\ldots c_8}) + \ldots\,,\\
\partial_t^2\phi &= \frac{3}{24\cdot 9!}e^{3\phi/2}P_{c_0|c_1\ldots c_8}P_{c_0|c_1\ldots c_8} + \ldots\,.
\end{aligned}\tag{D.6}$$

D.2 Comparison to the trombone gauged supergravity

We now compare the new contributions in the geodesic equations (D.5) and (D.6) to the equations of motion of the deformed supergravity where the trombone symmetry has been gauged [40, 41]. We use the equations given in equation (5.7) of [41] where we note that their dilaton has the opposite sign to ours. As is known, the equations of motion after a trombone gauging contain bare vector potentials, denoted by $\mathcal{A}_\mu$ in [41] and corresponding to our vector potential A_μ, together with the deformation parameter. This deformation parameter is denoted by m there but we call it M in order to avoid confusion with the Romans mass parameter. For this Appendix only we turn off the Romans deformation and consider instead the trombone deformation M. We do not know how to describe the terms containing the bare $\mathcal{A}_\mu$; we ignore these terms but instead focus on all contributions involving only the trombone deformation parameter M.

The relevant terms to be taken from (5.7) in [41] are then (after changing the sign of the dilaton)

$$\begin{aligned} D_\alpha(e^{3\phi/2}F^{\alpha\beta}) &= -12m\partial^\beta\phi + \dots\,, \\ D_\alpha(e^{\phi/2}F^{\alpha\beta_1\beta_2\beta_3}) &= 6me^{-\phi}F^{\beta_1\beta_2\beta_3} + \dots\,, \end{aligned} \tag{D.7}$$

for the form equations of motion and modified Bianchi identites (cf. (5.9) in [41])

$$4D_{[\alpha_1}F_{\alpha_2\alpha_3\alpha_4]} = -3mF_{\alpha_1\alpha_2\alpha_3\alpha_4} + \dots\,. \tag{D.8}$$

In the Einstein equation the correction is

$$R_{\alpha\beta} = 9m^2e^{-3\phi/2}\eta_{\alpha\beta} + \dots\,, \tag{D.9}$$

while there is *no* new term in the dilaton equation of motion.

Comparing the equations (D.7) and (D.8) to (D.5) one sees, upon use of the dictionary of Table 2 one sees that the new terms in the E_{10} equations (D.5) appear precisely in the right equations and with the correct dilaton prefactors in order to correspond to (D.7) and (D.8) if one made a dictionary of the type

$$P_{a_0|a_1\dots a_8} \sim e^{-3\phi/2}\epsilon_{a_0a_1\dots a_8}m\,. \tag{D.10}$$

However, the hook symmetry of the $(3,3)$ generator forbids the use of the epsilon. As discussed in Section 6 and in [42] there is no other way to associate a single parameter m to the hook tensor in an $SO(9)$ covariant way. We note that using the rough correspondence (D.10) in the Einstein equation of (D.6) will yield also a term with the correct dilaton prefactor compared to (D.9). In the dilaton equation, on the other hand, there is no new contribution from the trombone gauging in supergravity, indicating that the particular contraction in (D.6) would have to vanish. This is, however, not possible since it is a sum of squares.

Barring these difficulties we find it interesting that the hook generator appears in the right equations and also yields the right dilaton prefactor. Without a way of extracting a single deformation parameter m, we cannot confirm the association of the hook generator to the trombone gaugings.

One possible resolution of this puzzle was hinted at in Section 6 where it was suggested that in a vertex operator algebra based on the E_{11} root lattice one would obtain a new generator (associated with an imaginary simple root of the Borcherds algebra of physical states) on level $(3,3)$ that transforms as a nine-form under $SL(9,\mathbb{R})$. In a way similar to the discussion of the Romans mass one could associate a mass deformation parameter with this new generator. However, it being a new *simple* root it would not produce the same couplings to the lower level fields as in (D.3) but commute with them. Therefore, this possibility also seems ruled out as a resolution of the trombone gaugings.

E $\mathfrak{e}_{10}$ and $\mathfrak{k}(\mathfrak{e}_{10})$ at $\mathfrak{sl}(10,\mathbb{R})$ level 4

The decomposition of $\mathfrak{e}_{10}$ relevant for $D = 11$ maximal supergravity is the one associated to the exceptional node ℓ_1 in Figure 3. This is thus a decompositon with respect to the 'horizontal' $\mathfrak{sl}(10,\mathbb{R})$ subalgebra. At levels $\ell_1 = 1, 2, 3$ one obtains respectively a three-form $E^{a_1a_2a_3}$, a six-form $E^{a_1\cdots a_6}$ and a nine-index tensor $E^{a|b_1\cdots b_8}$ with mixed Young symmetry [8]. These generators have a natural interpretation as $D = 11$ supergravity fields following the dictionary derived in [8]. In this section only we use the convention that latin indices $a, b, c, \ldots$ are $\mathfrak{sl}(10,\mathbb{R})$-indices and hence run from 1 to 10.

Proceeding to level $\ell_1 = 4$ one obtains two distinct representations corresponding to the tensors $E^{a|b|c_1\cdots c_{10}}$ and $E^{a_1a_2a_3|b_1\cdots b_9}$, both with mixed Young symmetry [13,43]. Neither of these generators has a physical interpretation in terms of $D = 11$ supergravity degrees of freedom. However, as we have seen in the main text of this paper, upon further decomposion ('dimensional reduction') with respect to the node ℓ_2 in Figure 3 the generator $E^{a|b|c_1\cdots c_{10}}$ descends to the 'mass term generator' of massive type IIA supergravity in the following way [37,54] (see also (3.15))

$$E^{\alpha_1\cdots\alpha_9} := \frac{1}{8}E^{10|10|10\alpha_1\cdot\alpha_9}, \tag{E.1}$$

where $\alpha_i = 1, \ldots, 9$. Therefore, although no $D = 11$ interpretation exists for the full level 4 generators, in this way one obtains a physical interpretation of part of the level 4 representation content in the context of the massive IIA theory. In the main text we have analysed $\mathfrak{e}_{10}$ in a multilevel $\ell = (\ell_1, \ell_2)$ decomposition with respect to $\mathfrak{sl}(9,\mathbb{R})$, which directly reveals the spectrum of massive IIA supergravity. For completeness we shall in this appendix derive the commutation relations for $\mathfrak{e}_{10}$ at level 4 also in the $D = 11$ picture. Our results confirm a previous algorithmic computer algebra analysis in [43]. In addition we shall use our $\ell_1 = 4$ results to extend the $\mathfrak{k}(\mathfrak{e}_{10})$-representations **32** and **320** up to 'level 4'.

E.1 The $\mathfrak{e}_{10}$ commutation relations at level four

In the decomposition of the adjoint representation of $\mathfrak{e}_{10}$ in terms of representations of $\mathfrak{sl}(10,\mathbb{R})$ we find two tensors at level 4, both with mixed Young tableaux symmetries:

$$\begin{aligned} E^{a|b|c_1\cdots c_{10}} &= E^{(a|b)|[c_1\cdots c_{10}]}, \\ E^{a_1a_2a_3|b_1\cdots b_9} &= E^{[a_1a_2a_3]|[b_1\cdots b_9]}. \end{aligned} \tag{E.2}$$

Note that the first tensor can be simplified by pulling out the block of 10 antisymmetric indices,

$$E^{a|b|c_1\cdots c_{10}} = \epsilon^{c_1\cdots c_{10}} E^{a|b}. \tag{E.3}$$

In the following we shall use only $E^{s_1|s_2|c_1\cdots c_{10}}$ as it is more easily related to the mass of massive IIA supergravity. The second generator is also subject to the Young irreducibility constraint

$$E^{a_1a_2[a_3|b_1\cdots b_9]} = 0, \tag{E.4}$$

which is crucial in simplifying expressions involving this generator. To avoid an excess of indices in the text, we will often refer to the two level 4 generators schematically as $E^{1|1|10}$ and $E^{3|9}$, where the superscripts encode their respective index structures. Unless otherwise specified we shall throughout this section employ the convention that blocks of indices of the same type, e.g. $a_1, \cdots, a_r$, are implicitly *antisymmetrized*. For example,

$$E^{a_1a_2a_3|a_4\cdots a_9b_1b_2b_3} = E^{[a_1a_2a_3|a_4\cdots a_9]b_1b_2b_3}. \tag{E.5}$$

However, in cases where '0' is used as a subscript on an index, no antisymmetrization over this index is assumed, i.e., $E^{a_0a_1a_2|a_3\cdots a_8b_1b_2b_3} = E^{a_0[a_1a_2|a_3\cdots a_8]b_1b_2b_3}$. In addition, we let blocks of indices of 's'-type, i.e., $s_1\cdots s_r$, have implicit *symmetrization.*

We use slightly different conventions compared to [43], although we have checked that all our results are compatible with this reference. More specifically, our generators are related to the ones of [43] as follows

$$\begin{aligned} E^{a_1a_2a_3|b_1\cdots b_9} &= -\frac{210}{98}E_{[43]}^{a_1a_2a_3|b_1\cdots b_9}, \\ E^{s_1|s_2|a_1\cdots a_{10}} &= -12E_{[43]}^{s_1|s_2|a_1\cdots a_{10}}. \end{aligned} \tag{E.6}$$

The level $\ell_1 = 4$ generators can be obtained through commutators between generators at lower levels. Considering first the commutator between two level 2 generators, one finds that this yields only the generator $E^{3|9}$ at level 4, because no irreducible representation of $\mathfrak{sl}(10,\mathbb{R})$ which contains symmetric indices, as in $E^{1|1|10}$, can arise from the tensor product of two completely antisymmetric tensors. Thus, it is natural to define

$$[E^{a_1\cdots a_6}, E^{b_1\cdots b_6}] := E^{a_1a_2a_3|a_4a_5a_6b_1\cdots b_6} - E^{b_1b_2b_3|b_4b_5b_6a_1\cdots a_6}, \tag{E.7}$$

where the two terms on the right hand side are chosen in such a way that the antisymmetry of the commutator on the left hand side is taken into account. This relation can be inverted by using the irreducibility constraint (E.4) to give

$$E^{a_1a_2a_3|b_1\cdots b_9} = 42[E^{a_1a_2a_3b_1b_2b_3}, E^{b_4\cdots b_9}]. \tag{E.8}$$

We note that the ‘hook’-symmetry of the left hand side of this equation is matched also on the right hand side, as can be seen by employing ‘overantisymmetrization’ (also known a Schouten’s identity). For example, we have

$$[E^{a_1[a_2a_3b_1b_2b_3}, E^{b_4\cdots b_9]}] = 0 \quad \Rightarrow \quad [E^{a_1a_2[a_3b_1b_2b_3}, E^{b_4\cdots b_9]}] = 0. \tag{E.9}$$

The second level $\ell_1 = 4$ generator is generated from the commutator

$$\begin{aligned} [E^{a_1a_2a_3}, E^{b_0|b_1\cdots b_8}] \;&:=\; \big(E^{a_3|b_0|b_1\cdots b_8a_1a_2} + E^{a_3|b_8|b_1\cdots b_7b_0a_1a_2}\big) \\ &\quad + A\big(E^{b_0b_1b_2|b_3\cdots b_8a_1a_2a_3} - E^{b_1b_2b_3|b_4\cdots b_8b_0a_1a_2a_3}\big), \end{aligned} \tag{E.10}$$

where we have taken into account the mixed symmetry $E^{[b_0|b_1\cdots b_8]} = 0$ of the level 3 tensor. We take this as a definition of the generator $E^{1|1|10}$, explaining the absence of a pre-factor in the first term on the right hand side of (E.10). The coefficient A, however, is already fixed by (E.7) and the Jacobi identity and will be determined shortly.

This definition of $E^{s_1|s_2|a_1\cdots a_{10}}$ can be also inverted by a suitable projection, and we obtain

$$E^{s_1|s_2|a_1\cdots a_{10}} = \frac{10}{3}[E^{a_9a_{10}s_1}, E^{s_2|a_1\cdots a_8}], \tag{E.11}$$

where we made use of the convention, introduced above, that indices of ‘s’-type are implicitly symmetric. To arrive at (E.11) we also used the trick of overantisymmetrization on the indices $a_1\cdots a_{10}s_1$, which yields the following identity

$$E^{s_2|a_{10}|a_1\cdots a_9s_1} = \frac{1}{10}E^{s_1|s_2|a_1\cdots a_{10}}. \tag{E.12}$$

The coefficient A can now be fixed by requiring consistency, which in this case amounts to invoking the Jacobi identity. We shall need the following relations (recall our conventions for implicit antisymmetrization on indices of the same kind)

$$\begin{aligned} [E^{a_1a_2a_3}, E^{a_4a_5a_6}] &= E^{a_1\cdots a_6} \\ [E^{a_1a_2a_3}, E^{b_1\cdots b_6}] &= E^{a_1|a_2a_3b_1\cdots b_6}. \end{aligned} \tag{E.13}$$

Using the Jacobi identity we may then write (E.8) as

$$E^{a_1a_2a_3|b_1\cdots b_9} = -42[E^{b_1b_2b_3}, E^{a_1|a_2a_3b_4\cdots b_9}]. \tag{E.14}$$

Now, by inserting (E.10) on the right hand side we find that this equation is only satisfied for the unique value

$$A = -\frac{28}{5}. \tag{E.15}$$

Thus, equation (E.10) becomes

$$\begin{aligned} [E^{a_1a_2a_3}, E^{b_0|b_1\cdots b_8}] \;&=\; \big(E^{a_3|b_0|b_1\cdots b_8a_1a_2} + E^{a_3|b_8|b_1\cdots b_7b_0a_1a_2}\big) \\ &\quad + \frac{28}{5}\big(E^{b_1b_2b_3|b_4\cdots b_8b_0a_1a_2a_3} - E^{b_0b_1b_2|b_3\cdots b_8a_1a_2a_3}\big). \end{aligned} \tag{E.16}$$

Finally, from our definitions (E.7) and (E.16) and invariance of the bilinear form, we deduce that the level 4 generators have the following normalisation:

$$\begin{aligned}\left\langle E^{a_1a_2a_3|b_1\cdots b_9}|F_{c_1c_2c_3|d_1\cdots d_9}\right\rangle &= (6\cdot 7!)^2\left(45\delta^{a_1\cdots a_3}_{c_1[d_1d_2}\delta^{[b_1\cdots b_7}_{d_3\cdots d_9]}\delta^{b_8b_9]}_{c_2c_3} - 10\delta^{a_1\cdots a_3}_{[d_1\cdots d_3}\delta^{[b_1\cdots b_6}_{d_4\cdots d_9]}\delta^{b_7\cdots b_9]}_{c_1\cdots c_3}\right)\\ \left\langle E^{s_1|s_2|a_1\cdots a_{10}}|F_{r_1|r_2|b_1\cdots b_{10}}\right\rangle &= 64\cdot 10!\,\delta^{(s_1}_{r_1}\delta^{s_2)}_{r_2}\,\delta^{a_1\cdots a_{10}}_{b_1\cdots b_{10}}\,. \qquad \text{(E.17)}\end{aligned}$$

E.2 The Dirac-spinor representation ϵ of $\mathfrak{k}(\mathfrak{e}_{10})$

We proceed to define the $\mathfrak{k}(\mathfrak{e}_{10})$-generators at 'level 4' as

$$\begin{aligned}J^{s_1|s_2|a_1\cdots a_{10}}_{(4)} &= E^{s_1|s_2|a_1\cdots a_{10}} - F_{s_1|s_2|a_1\cdots a_{10}},\\ J^{a_1a_2a_3|b_1\cdots b_9}_{(4)} &= E^{a_1a_2a_3|b_1\cdots b_9} - F_{a_1a_2a_3|b_1\cdots b_9}, \qquad \text{(E.18)}\end{aligned}$$

with the $\mathfrak{k}(\mathfrak{e}_{10})$-generators at levels 0, 1, 2 and 3 defined similarly. As for the $\mathfrak{e}_{10}$-generators at level 4 we will sometimes denote these generators by $J^{1|1|10}_{(4)}$ and $J^{3|9}_{(4)}$. We want to find how they act on the object ϵ, which is a 32-dimensional spinor representation of $\mathfrak{k}(\mathfrak{e}_{10})$. Subsequently, we shall generalize this to the 320-dimensional vector-spinor representation Ψ.

For the levels 0, 1, 2 and 3 generators we have [17–19, 21]

$$\begin{aligned}M^{a_1a_2}\cdot\epsilon &= \frac{1}{2}\Gamma^{a_1a_2}\epsilon,\\ J^{a_1a_2a_3}_{(1)}\cdot\epsilon &= \frac{1}{2}\Gamma^{a_1a_2a_3}\epsilon,\\ J^{a_1\cdots a_6}_{(2)}\cdot\epsilon &= \frac{1}{2}\Gamma^{a_1\cdots a_6}\epsilon,\\ J^{a_0|a_1\cdots a_8}_{(3)}\cdot\epsilon &= 12\delta^{a_0a_1}\Gamma^{a_2\cdots a_8}\epsilon. \qquad \text{(E.19)}\end{aligned}$$

The extension of this representation to level 4 can be obtained by considering the commutators $\left[J_{(1)},J_{(3)}\right]$ and $\left[J_{(2)},J_{(2)}\right]$. Schematically, they have the following structures

$$\begin{aligned}\left[J_{(1)},J_{(3)}\right] &= J_{(2)} + J^{1|1|10}_{(4)} + J^{3|9}_{(4)},\\ \left[J_{(2)},J_{(2)}\right] &= M + J^{3|9}_{(4)}, \qquad \text{(E.20)}\end{aligned}$$

where the $J^{1|1|10}_{(4)}$ generator is absent from the second commutator because of (E.7).

We can then derive $J^{a_1a_2a_3|b_1\cdots b_9}_{(4)}$ by using the projection (E.8), which yields

$$\begin{aligned}J^{a_1a_2a_3|b_1\cdots b_9}_{(4)}\cdot\epsilon &= 42\left[J^{a_1a_2a_3b_1b_2b_3}_{(2)},J^{b_4\cdots b_9}_{(2)}\right]\cdot\epsilon\\ &= -42\cdot 60\delta^{a_1a_2a_3}_{b_1b_2b_3}\Gamma_{b_4\cdots b_9}\epsilon + 42\cdot 9\delta^{a_1}_{b_1}\Gamma^{a_2a_3}{}_{b_2\cdots b_9}\epsilon. \qquad \text{(E.21)}\end{aligned}$$

We now proceed to the other level 4 generator, $J^{1|1|10}_{(4)}$. This arises from the commutator

$$\left[J^{a_1a_2a_3}_{(1)},J^{b_0|b_1\cdots b_8}_{(3)}\right]\cdot\epsilon. \qquad \text{(E.22)}$$

Using the projection in (E.11) yields

$$J_{(4)}^{s_1|s_2|a_1\cdots a_{10}} \cdot \epsilon = \frac{10}{3}\left[J_{(1)}^{a_9 a_{10} s_1}, J_{(3)}^{s_2|a_1\cdots a_8}\right] \cdot \epsilon = 10 \cdot 4\delta^{s_1}_{a_1}\Gamma^{s_2}{}_{a_2\cdots a_{10}}\epsilon. \tag{E.23}$$

We may now use equation (E.12) to rewrite (E.23) as

$$J_{(4)}^{s_1|s_2|a_1\cdots a_{10}} \cdot \epsilon = 4\,\delta^{s_1 s_2}\Gamma^{a_1\cdots a_{10}}\epsilon. \tag{E.24}$$

E.3 The vector-spinor representation Ψ of $\mathfrak{k}(\mathfrak{e}_{10})$

Let us now move on to the 320-dimensional vector-spinor representation Ψ of $\mathfrak{k}(\mathfrak{e}_{10})$. In $\mathfrak{so}(10)$ language it is written as Ψ_a. For the levels 0, 1, 2 and 3 generators we have [18,19,21]

$$\begin{aligned}
M^{a_1a_2} \cdot \Psi_b &= \frac{1}{2}\Gamma^{a_1a_2}\Psi_b + 2\delta^{a_1}_b\Psi^{a_2}, \\
J_{(1)}^{a_1a_2a_3} \cdot \Psi_b &= \frac{1}{2}\Gamma^{a_1a_2a_3}\Psi_b + 4\delta^{a_1}_b\Gamma^{a_2}\Psi^{a_3} - \Gamma_b{}^{a_1a_2}\Psi^{a_3}, \\
J_{(2)}^{a_1\cdots a_6} \cdot \Psi_b &= \frac{1}{2}\Gamma^{a_1\cdots a_6}\Psi_b - 10\delta^{a_1}_b\Gamma^{a_2\cdots a_5}\Psi^{a_6} + 4\Gamma_b{}^{a_1\cdots a_5}\Psi^{a_6}, \\
J_{(3)}^{a_0|a_1\cdots a_8} \cdot \Psi_b &= \frac{16}{3}\big(\Gamma_b{}^{a_1\cdots a_8}\Psi^{a_0} - \Gamma_b{}^{a_0a_1\cdots a_7}\Psi^{a_8}\big) + 12\delta^{a_1}_{a_0}\Gamma^{a_2\cdots a_8}\Psi_b \\
&\quad -168\delta^{a_1}_{a_0}\Gamma_b{}^{a_2\cdots a_7}\Psi^{a_8} - \frac{16}{3}\big(\delta^{a_1}_b\Gamma^{a_2\cdots a_8}\Psi^{a_0} \\
&\quad -8\delta^{a_0}_b\Gamma^{a_1\cdots a_7}\Psi^{a_8} - 7\delta^{a_1}_b\Gamma_{a_0}{}^{a_2\cdots a_7}\Psi^{a_8}\big).
\end{aligned} \tag{E.25}$$

We proceed in the same way as before, and derive the $J_{(4)}^{3|9}$-generator from the commutator $\left[J_{(2)}, J_{(2)}\right]$. Using (E.25) we must compute

$$\left[J_{(2)}^{a_1\cdots a_6}, J_{(2)}^{b_1\cdots b_6}\right] \cdot \Psi_c. \tag{E.26}$$

Performing this calculation and projecting onto $J_{(4)}^{a_1a_2a_3|b_1\cdots b_9}$ using (E.8) then yields[23]

$$\begin{aligned}
J_{(4)}^{a_1a_2a_3|b_1\cdots b_9} \cdot \Psi_c &= 42\left[J_{(2)}^{a_1a_2a_3b_1b_2b_3}, J_{(2)}^{b_4\cdots b_9}\right] \cdot \Psi_c \\
&= -50400\delta^{a_1a_2a_3c}_{b_1b_2b_3b_4}\Gamma_{b_5\cdots b_8}\Psi_{b_9} - 5040\delta^{a_1a_2c}_{b_1b_2b_3}\Gamma_{b_4\cdots b_9}\Psi^{a_3} \\
&\quad +30240\delta^{a_1a_2c}_{b_1b_2b_3}\Gamma^{a_3}{}_{b_3\cdots b_8}\Psi_{b_9} + 25200\delta_c{}^{a_1a_2a_3}{}_{b_1b_2}\Gamma_{b_3\cdots b_8}\Psi_{b_9} \\
&\quad +40320\delta^{a_1a_2a_3}_{b_1b_2b_3}\Gamma_{b_4\cdots b_8c}\Psi_{b_9} + 5040\delta^{c\ a_1}_{b_1b_2}\Gamma^{a_2}{}_{b_3\cdots b_9}\Psi^{a_3} \\
&\quad -2520\delta_c{}^{a_1a_2}{}_{b_1}\Gamma_{b_2sb_9}\Psi^{a_3} + 5040\delta^{a_1a_2}_{b_1b_2}\Gamma_{b_3\cdots b_9c}\Psi^{a_3} \\
&\quad -25200\delta^{ca_1}_{b_1b_2}\Gamma^{a_2a_3}{}_{b_3\cdots b_8}\Psi_{b_9} - 5040\delta^{a_1a_2}_{cb_1}\Gamma^{a_3}{}_{b_2\cdots b_8}\Psi_{b_9} \\
&\quad +5040\delta^{a_1a_2}_{b_1b_2}\Gamma^{a_3}{}_{b_3sb_8c}\Psi_{b_9} + 672\delta^{a_1}_c\Gamma^{a_2}{}_{b_1\cdots b_9}\Psi^{a_3} \\
&\quad -4032\delta^{a_1}_{b_1}\Gamma^{a_2}{}_{b_2\cdots b_9c}\Psi^{a_3} - 2688\delta^c_{b_1}\Gamma^{a_1a_2a_3}{}_{b_2\cdots b_8}\Psi^{a_3} \\
&\quad -2016\delta^{a_1}_c\Gamma^{a_2a_3}{}_{b_1\cdots b_8}\Psi_{b_9} - 16128\delta^{a_1}_{b_1}\Gamma^{a_2a_3}{}_{b_2\cdots b_8c}\Psi_{b_9} \\
&\quad -2520\delta^{a_1a_2a_3}_{b_1b_2b_3}\Gamma_{b_4\cdots b_9}\Psi_c + 378\delta^{a_1}_{b_1}\Gamma^{a_2a_3}{}_{b_2\cdots b_9}\Psi_c.
\end{aligned} \tag{E.27}$$

---

[23] In doing this calculation the computer package GAMMA [71] proved to be very useful.

We compute the action of $J_{(4)}^{s_1|s_2|a_1\cdots a_{10}}$ by projection, as in (E.23), with the result

$$\begin{aligned}
J_{(4)}^{s_1|s_2|a_1\cdots a_{10}} \cdot \Psi_b &= \frac{10}{3}\left[J_{(1)}^{a_9 a_{10} s_1}, J_{(3)}^{s_2|a_1\cdots a_8}\right] \cdot \Psi_b \\
&= -\frac{2960}{3}\delta_b^{s_1}\delta_{a_1}^{s_2}\Gamma_{a_2\cdots a_9}\Psi_{a_{10}} - \frac{640}{3}\delta_{s_2}^{s_1}\delta_{a_1}^{b}\Gamma_{a_2\cdots a_9}\Psi_{a_{10}} \\
&\quad +\frac{10880}{3}\delta_{a_1 a_2}^{b\ s_1}\Gamma^{s_2}{}_{a_3\cdots a_9}\Psi_{a_{10}} + \frac{2800}{3}\delta_{a_1 a_2}^{b\ s_1}\Gamma_{a_3\cdots a_{10}}\Psi^{s_2} \\
&\quad +\frac{640}{9}\delta_{s_2}^{s_1}\Gamma_{a_1\cdots a_9 b}\Psi_{a_{10}} - \frac{1280}{9}\delta_{a_1}^{b}\Gamma_{a_2\cdots a_{10}}{}^{s_1}\Psi^{s_2} \\
&\quad +\frac{640}{3}\delta_b^{s_1}\Gamma^{s_2}{}_{a_1\cdots a_9}\Psi_{a_{10}} - 1600\delta_{a_1}^{s_1}\Gamma^{s_2}{}_{a_2\cdots a_9 b}\Psi_{a_{10}} \\
&\quad +\frac{640}{9}\delta_b^{s_1}\Gamma_{a_1\cdots a_{10}}\Psi^{s_2} + \frac{3520}{9}\delta_{a_1}^{s_1}\Gamma_{a_2\cdots a_{10} b}\Psi^{s_2} \\
&\quad +40\delta_{a_1}^{s_1}\Gamma^{s_2}{}_{a_2\cdots a_{10}}\Psi_b. \qquad \text{(E.28)}
\end{aligned}$$

We note that upon a further level decomposition with respect to ℓ_2, these expressions for the action of $\mathfrak{k}(\mathfrak{e}_{10})$ on the vector-spinor representation in the A_9 level decomposition are consistent with the analogous expressions for the A_8 decomposition in eqs. (B.15) and (B.16). In particular, we see from (3.15) that

$$J_{(4)}^{10|10|10\,\alpha_1\cdots\alpha_9} = 8J_{(4,1)}^{\alpha_1\ldots\alpha_9}, \qquad \text{(E.29)}$$

where $\alpha_i = 1, \ldots, 9$, and one can check explicitly that the actions on both vector-spinor and Dirac-spinor agree.
